17978. Sloping Front Box for DDS VFO for the TR7

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-01-01 17:33:58 UTC
From: k3jls@verizon.net
Topic: 17978 Message: 17978

Hello,

If anyone is interested, there's a nice sloping front box for sale on ebay that will provide a spiffy enclosure for an external DDS VFO or the TR7.

Here's the link: http://www.ebay.com/itm/SE453N-4-Aluminum-Sloped-Instrument-Console-Enclosure-Case-Box-for-DIY-/251202040489?pt=US_Pro_Audio_Parts_Accessories&hash=item3a7ccef2a9

This seller has 3 left and I just bought one for another external DDS VFO that I'll be selling on eBay.

I expect to have the new batch of P/C boards this Friday along with the parts to build 2 more units, one of which will be installed in my TR7 proper.

Details, the M/P code and a parts list are on my website - www.k3jls.net/tentec.html

73's - Joe - K3JLS

17979. What the L?

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-01-02 02:16:37 UTC
From: Paul Kraemer
Topic: 17979 Message: 17979

In the last couple weeks I have been asked by several people working on
their AC-4 supplies what the inductance value of the little line chokes is.
Don't know I have ever seen it listed so I measured one
L=0.016 millihenry @ test frequency of 120hz
Now we have a number for whatever it's worth.
I have seen similar units in Mouser if anyone needs to replace one
Happy New Year to all and to all a good night!
Paul K0UYA

17980. Re: [DrakeRadio] What the L?

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-01-02 02:20:54 UTC
From: Steve Wedge
Topic: 17979 Message: 17980

That's another part that is in some but not all AC-4's. I just rebuilt one that must have been "transitional", but it had no chokes.

It's plugged into my C-4 power controller, though, to which I added a very heavy-duty Cor-Com line filter years ago, so my AC lines are pretty much filtered anyway

Steve Wedge, W1ES/4

From: bobbyb@frontiernet.net
Topic: 17981 Message: 17981

Excellent cosmetic condition

powers up and tested tx into a dummy load 100W on 40 and 80.

R-4C has 3 drake filters mounted on the back

I purchased these from a fellow ham a while ago with other gear.

I am redoing the shack and decided to stay with my dual kenwood TS-430 set up for now. with an external Icom R-75 on the primary station.

This means the Drakes , the swans, and the yeasu gear needs to go...

station can be tested in Washingtonville, NY.

I paid a fair price for the gear, Please make a fair offer and they will be yours. I can pack and ship. I own a hobby shop and ship daily. They will be bubblepacked, boxed, then inserted in an overpack box with padding. shipped fully insured with signature conf. Buyer pays actual shipping costs.

K3RJB [qrz info is current.]

bobbyb@...
yes I have pics available on request.

no, I am not breaking them up YET.... if they do not sell here in a few days or so they will be on FEEBAY and priced accordingly....

Bobby B

? reviewing? the schematic for the upper and lower crystal filters and see?; the crystal filters are reversed?compared to the schematic.removed one filter? to verify which is used in lsb.found the one used in lsb is marked? model no. 5.645-2.4U? and? the usb mode is wired to? model no. 5.645-2.4L?? are these filters? wired up reversed.do you need the 2.4u I for usb? and the 2.4l for lsb? audio is great in usb but in lower sb very narrow.? ready to replace the lsb filter from steve, but want to ask before replacing the filter. tom? wk6f

???? I've been following this but don't remember exactly what you have done so far.? Its important that the frequency of the carrier oscillator be centered between the two filters. There is a trimmer for this.? The handbook procedure is to unbalance the balanced modulator using the variable resistor and look at the residual carrier on a scope or receiver with s-meter.? A scope is probably better.? The carrier oscillator frequency is them adjusted to get the same amount of residual carrier when the sideband switch is changed from one to the other. This puts the carrier at the same point on the skirts of the two filters.? The modulator is than re-balanced for minimum residual carrier.? After doing this adjustment the quality of the audio should be the same on the two sidebands.?? If it is not one or both of the filters may be bad. Ideally, the receiver used for checking should be one without a sharp IF filter of its own and, again ideally, a receiver with a very wide and symmetrical passband so that the receiver characteristics do not mask the transmitter performance.?
???? According to the graphs in the handbook the two filters have the same shape factor and are symmetrical around their center frequencies but the center frequencies are different.
???? Note that if the transformers in the IF are not correctly adjusted they could give the effect of the sideband filters not being symmetrical.? The instructions in the handbook are reasonably easy to follow and, even if you have already done this, its worth doing again just to make sure.?
???? The filters can probably be checked for response in place but I have not done this.?; Perhaps Garey can suggest a good method.? It IS possible for the filters to go bad? but I would double check everything else before getting replacements.?? I have checked my T4XB many times using both an SP-600-JX and an RCA AR-88 both of which have very wide IF filters and find the quality is exactly the same on the two sidebands. Because of the wide, symmetrical, passband I can switch sidebands without retuning.

From: Garey Barrell
Topic: 17982 Message: 17986

The sideband is inverted in the first mixer on all 4 series transmitters because of the LO / IF arrangement. An LSB signal applied to the first mixer comes out as USB at the output frequency.

Okay, then if he's having trouble with the ssb filter, in LSB, which filter would be replaced? the one appended "U" or "L"?

Maybe the reason is that the 4-Line INVERTS THE IF when mixing up to the TX-Signal. The Output of the premixer is higher than the IF 5.6MHZ. So "LSB" on 5.6MHz is "USB" at the TX-output

Steve -

Correct. I can never remember the 'rule', and have to figure it out each time. If the 'RF and IF are both below the
LO, then the IF is inverted'. So if we have a USB signal, consisting of 5.645 MHz RF and a single tone of 5.646, (1
kHz tone), and an LO of 12.645 MHz, the difference frequency is going to be 6.999 MHz, or 1 kHz Lower Sideband..

So the 'Sideband Generator' outputs a USB signal, from the USB filtered DSB signal, which is then inverted in the 1st
Mixer to an LSB signal. Since this relationship is maintained on all bands in the
T-4X(any), this holds true for all.

As a comparison, if you have a 9 MHz RF with single tone at 9.001 MHz, (USB) and an LO of 5.000 MHz, (LO 'above' the
IF) the output will be 4.001 MHz, still USB. The sum, 9.001 MHz and 5.000 MHz will also output 14.001 MHz or USB.
However if you turn things around, i.e., 5.001 MHz RF (USB) and LO of 9.000 MHz, the difference becomes 3.999 MHz (LSB)
(inverted). Likewise, for 5.001 MHz (USB) and 9.000 MHz, the sum is 14.001 MHz also USB!

So if EITHER the RF -or- LO is 'above' the IF, it's NOT inverted.

I 'think' that's right!!!! :-)

Anyway, if the T-4X(any) has a problem putting out USB, it's the LSB filter that's at fault!

17993. R-4C Dial Repair

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-01-03 17:11:05 UTC
From: <dcoffman@...>
Topic: 17993 Message: 17993

I'm in the process of refurbishing an R-4C that I received a couple of weeks ago. One of the previous owners used the thickest grease that I have ever seen, significantly thicker than wheel bearing grease, on the plastic PTO gears, between the dial plates, and on the PTO threaded shaft. The grease, impregnated with dirt, has scarred the dial plates all the way out to the numbers; the grease was even on the blue filter material. After several hours with Simple Green and Dawn dish soap, I was able to remove the bulk of the junk from the plastic parts; the metal parts required Q-Tips and diesel fuel.

The question I have is has anyone successfully removed scratches from the dial plates. I have tried headlight lens restorer, I event attempted to apply some heat to the effected areas in an attempt to melt the scratches and chickened out. I have not made the situation worse but I did not see any real improvement with what I have tried.

My buddy Joe mentioned that someone had put out some feelers for possibly creating some reproductions; has anyone made such a dial?

Thanks,

Doug - N9XTF

You might try MacQuires(sp?) plastic polish for motorcycle windshields - usually available at auto parts stores, I've used it on my cel phone display window. It has both a polishing cleaner and surface smoothing wax in it.

Also, if the scrathes are not too deep, Sensodyne toothpaste applied with your fingers - works to polish CD's and DVD's, but takes a long time.

I have successfully used the Novus polishes available from Antique Electronic Supply. For shallow scratches.

I have also used toothpaste. In astronomy, rouge and/or cerium oxide is used for fine polish, with coarse grit leading up to the final stage. I have had to use rubbing compound on some deep scratches to remove them, then go to more fine polishes. If too much surface is removde around the deep scratch, then a slight distortion will remain after polish....but to me this "goes away" after time and I don't notice it.

In all cases, Doug, it required a good bit of elbow power. Hope some of this helps.

Wes

17996. Transformer Rewinding

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-01-03 19:15:26 UTC
From: <cavemaaan@...>
Topic: 17996 Message: 17996

Hey All :)

I'm hoping someone here can help me even though this is not directly Drake related. I'm trying to get a small power transformer rewound as it has an issue and will blow a fuse after running for around eight seconds by itself. This is the power tranny for an older Wavtek SSI-3000 radio service monitor. The tranny is impossible to replace with new due to the HV winding for a modulation CRT....trust me I've looked for months once I obtained the basic specs of the tranny.

I thought I had found a guy, Gary Brown from "Transformer Rewinding Service" in Orono, ME, but no one is responding to email from four weeks ago and when I tried to call yesterday, the phone number listed is no longer valid.

It seems he was the only small tranny repair person I could find - everything else that comes up on Google search is a large-to-huge electrical grid transformer repair place for multi-kilovolt trannies.

Does anyone know of anyone who rewinds without leaving me broke?

Thanks,
Dan Gibbs

Hi Dan,
Gary & I corresponded in Nov., his email is XFRMRS@... He
rewound a plate xfmr I sent him then. Don't have his fone nr, but can
get it from a mutual friend.

Dan,
I have dealt with Gary on a few occasions, and feel safe in relating this observation. He is not "web-centric". While I imagine that business he gets through his website, is a significant portion of his business, I don't think he is one to check his email several times a day, or even daily. In my experience, it has sometimes taken him several days, to answer. That, and given the time of year, people's tendency to travel, at this time of year, and the travel delays, brought on by the current winter storm, gripping the northeast, I'd give it a few more days, to hear back. He might be stuck at a Florida airport, awaiting the next flight available to Maine. Or, he could be stuck at the Bangor airport, unable to traverse the roads back to Orono.

BTW, it's nice to have a group, that is relaxed, yet helpful enough, that nobody gets their wrist slapped, because a question is asked that is not about the particular brand, that is the focus of the reflector. Yet, they still get answers to their question.

Doug,

There is a product out there called "Blue Magic" which works wonders on such things. I use it regularly when restoring R390A's to remove the scratches and yellowing from the odometer readout plastic dial "glass" and it also cleans the stainless steel front panel handles. Its also done wonders to remove any trace of scratches from the "crystal" of my EDC wrist watch.

I use it with a buffer wheel on a drill press, set to turn about 600 RPM. Wouldn't go much faster with it.

You may be able to find it locally, but know that while Blue Magic make a number of products, THIS is what you want:

http://www.amazon.com/gp/product/B000ALCOCQ/ref=oh_details_o04_s00_i01?ie=UTF8&psc=1

It also works wonders on cleaning up Drake and "S" Line knobs, removing the oxidization then polishing the plastic.

If you want, mail me off list, you can send me the dials and I'll do my best to take the scratches out.

Charles,

I did not see your email address to reply to directly.

Strangely enough, for what reason I do not know, I had a fresh bottle of Blue Magic in my garage. I had tried this product before the post to the group however; I tried it by hand for a couple of hours and did not touch the scratches.

I just finished a couple of hours on your approach. I put a buffing pad on my hand held drill and set it for about 600 RPM; half of full speed. I gently went over both dials, front and back, and successfully removed all of the deep scratches. This however left a pretty significant haze. I then made up a solution of dish soap and water and continuiously soaked the buffing pad while buffing the discs again. I cut the haze down by ¾, they look very good but there is still a haze present. I have tried hand buffing with tooth paste but just can□t quite get rid of the haze. I also tried hand buffing the discs with the Blue Magic.

If I could keep the discs a little damp they look brand new!!!

Yes, the filters are installed correctly. See my earlier message.
If you have an audio oscillator you can apply it to the MIC input. Then in SSB sweep the audio from 100 Hz to 3500 Hz. The output should rise from zero at 100 Hz to maximum at about 400 Hz, stay fairly level until about 2800 Hz, then fall rapidly to zero again. If the output drops significantly in between those two frequencies, you have A bad filter. Repeat on both sidebands.

18004. AC-3 240 mains conversion?

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-01-03 23:11:10 UTC
From: <vk2sja@...>
Topic: 18004 Message: 18004

Hi All,

Name is Steve, VK2SJA QTH Nowra NSW Australia.

First post to the group but I've been lurking for a few weeks. Reading and learning lots!

I am starting the process of restoring my recently acquired TR-4C and a AC-3 PSU (from separate sources). I ordered the ES4AC-3 upgrade kit and this morning started examining the AC-3 circuit. Don't like what I'm seeing.

The AC-3 manual states (and circuit diagram shows) that the PSU can be used on either 110v or 240v AC. For 110v mains the primary is two windings in parrallel. For 240v mains (which we use here in VK) you wire the same two windings in series.

Problem. I only appear to have *two* primary fly-leads and not four. Manual shows Black+Black/White as one priimary and then Black/Red+Black/Green as the second primary winding. I was expecting to find all four of these wires going to a terminal strip. But what I have is two white wires only (inside black cloth insulation).

The AC-3 power supply is S/N 8209 and the transformer has A-10180 3946409 written on it.

Questions:

Did Drake manufacture a number of power supplies with a transformer suitable only for the domestic 110v market?

If I cut away the most outer layer of winding insulation am I going to find the two priimary windings hidden inside?

Does anyone have a AC-3 or AC-4 which can be modified for 240v mains operation (Not working is fine. The transformer is the only important thing) that they can sell me?

73, Steve

I've not worked with Drake dials, but I've used toothpaste to polish clear plastic LCD lenses, as well as other plastic parts.
I've had no problem getting the clear stuff so close to perfect, that you would have to nearly stare at it to see a problem.
So I rather doubt that you should have a problem getting the haze off those dials.
You might want to try a different toothpaste(they DO vary).
Generally, mixing it with a bit of water is helpful(the paste toothpastes generally need more water than the gel toothpastes).
Try using folded paper toweling or cloth to apply and buff it in.
Then try a piece of DRY paper for the final polish-first brown, then white.

I think that Hammond in Ontario Canada can do that or at least they used to. They rewound a L4B transformer many years ago. They also can make customs transformers etc. Look here and read the FAQ's.

Hi all,

I'm working on building an accessory for my R-4 receiver and would like to match the front panel paint colors as closely as possible. I looked through the old messages, but couldn't find anything....not that it's not there!

Does anyone have any specific recommendations (preferably in rattle-cans) for the two grays on the 4-line Drakes?

Which colors for the Drake front panel? Are you airbrushing, or are these
available in cans?

BTW airbrushing allows for closer color matching and closer matching finishes.

Subject: [DrakeRadio] Paint Colors

Hi all,

I'm working on building an accessory for my R-4 receiver and would like to match the front panel paint colors as closely as possible. I looked through the old messages, but couldn't find anything....not that it's not there!

Does anyone have any specific recommendations (preferably in rattle-cans) for the two grays on the 4-line Drakes?

Thanks - I understand that, but I don't currently have access to an
airbrush.

Perhaps I should have phrased my question differently - instead of "as
close as possible" I should have said "as close as practical, but
relatively easy to implement using spray paints from Home Depot, Menards,
etc." ;-)

I'm not looking to refinish to an exact match, but to get fairly close...

http://en.wikipedia.org/wiki/Single-sideband_modulation

Illustration of the spectrum of AM and SSB signals.
The lower side band (LSB) spectrum is inverted compared
to the baseband. As an example, a 2 kHz audio baseband
signal modulated onto a 5 MHz carrier will produce a
frequency of 5.002 MHz if upper side band (USB) is used
or 4.998 MHz if LSB is used.

If I understand what you are asking the answer is "it depends on the design of the radio". Some radios will shift carrier frequency dial calibration when you change modes, others will read true. Rigs that use a single crystal filter for SSB will change dial calibration when switching modes unless steps are taken elsewhere in the mixing scheme to compensate. Look at some of the older Kenwood and Yaesu rigs, you will see fiducial markings for each sideband on the bezel. Rigs that use separate filters for USB and LSB *should* maintain a true reading when changing modes.

Hey All....Gary contacted me via email today while I was at work (second shift).

Thanks for all of the replies....they are greatly appreciated :)

I've known of Hammond Mfg for twenty years now but never knew the did rewinding - I just figured that they could do a one-off custom, but it would cost waaay too much just like Northlake Eng told me (they made the original and said $1,000 for a one-off)

I have known of Heyboer for about seven years now - Alden (nice guy) helped by selling me some thermal fuses to repair the power tranny in my older Fender Twin guitar amp. I tried to call him today but they were closed by the time I tried to call.

Thanks for the help - I know it wasn't directly about Drake, but I can use it to check my Drakes when it's fixed :)

performed carrier osc,filter match,and balancd mod. alignment now see no change with vfo setting and audio quality in lower and upper ssb modes. listened with a yaesu ft1000mpk5 with wide receive in both ssb modes.sounds good. I believe the crystal filters are good on lower side band. need to make a few contacts. Tom WK6F let everyone know what I find. tom wk6f

18022. PROMmania! U9003 cracked!

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-01-04 05:40:26 UTC
From: Jim Shorney
Topic: 18022 Message: 18022

With many thanks to Garey, Bob Macklin, and Jim Pruitt for their help I can now supply replacement U9003 PROMs for the DR-7 board in the TR-7 (they should work in the R-7 as well). This is using the 74S387 device, for which I found a good supply of 1994-dated NOS chips at a reasonable cost.

I have made a couple of changes to the original Drake code:

WARC bands (30, 17, and 12 Meters) are now flagged as "Ham Bands". For most of us I imagine this will be enhanced uselessness, but what it will do is allow an unmodified TR-7 without an AUX-7 to transmit in the WARC bands. You do not need the allband transmit hack (parent board trace cut) mod, the GW4ALG "almost allband" mod, or my "better allband transmit mod" to use the WARC bands.

60 Meter transmit will also be possible, but a mod to the Digital Control PCB will still be needed.

The unused third bit has been programmed to toggle on the three lowest band segments for 0.0-1.5 MHz. I figure that clever folks might find this useful to switch external VLF accessories. This bit can be custom programmed to switch on any band segment or segments by request if someone comes up with another interesting idea to make use of it.

The first sample off the burner has been tested in my spare TR-7 and works as expected.

For those of you (and I know who you are) who were involved in the recent conversation about U9003 that sparked this adventure and who expressed an interest in acquiring PROMs for your own needs, please contact me OFF-LIST if you are still interested. I will offer a special one-time low price for your personal use or spares only. That is, I don't want to see them showing up for sale on eBay or other places. After that, capitalism will kick in and I will be asking a fair price in hopes of at least eventually recovering what I have invested in this project.

(Garey, stop reading now)

I also have a limited supply of 16-pin ROBINSON NUGENT ICA163SA milled pin IC sockets available if you want one with your PROM. These are the non-gold version.

Again, contact me OFF-LIST.

Glad you are seeing some progress, Doug. I've never had any hazing issues
but there may be differences in plastic formulations, etc..... Maybe now
is the time to try some tooth paste in a small spot and see what happens.

When you get this dial issue behind you, try that buffing wheel/Blue Magic
combo on the knobs. Its amazing.

Sometimes getting the cosmetic issues cured is 2X as hard as the
electronics.

Changing sidebands on _SSB_ does NOT change the (suppressed) Carrier frequency. What may be confusing you is that in
TUNE mode, the transmitter applies an approximately 1 kHz tone (think whistling into the microphone), and the output
frequency of the transmitter is then 1 kHz above (or below) 7.150 depending upon whether you are in USB or LSB. But the
(suppressed) Carrier frequency does NOT change.

In _CW_ mode however, the Carrier Oscillator IS shifted approximately 1 kHz UP, into the passband of the LSB filter
(indicated by the "X" associated with those switches), and the Balanced Mixer is unbalanced so that the CO signal can
pass through with minimal attenuation to be amplified as the OUTPUT signal. This is why the OUTPUT frequency of the
transmitter is about 1 kHz BELOW the dial frequency indicated.

Tom -

Think of the Car Osc and filters as the letter "M". The Car Osc should be centered in the 'bottom' of the V in the middle. The two peaks of the M represent the two sideband filter bandwidths. The two peaks actually have a flat top, and visualize them as 0 Hz at the bottom of the V and say 4 kHz on the outer ends of the two peaks.

So... if the Car Osc is exactly centered, each side(band) will have a flat top approximately 2.4 kHz wide, say 400 to 2800 Hz. If the Car Osc is OFF center by 100 Hz, then one flat top will be from 500 Hz to 2900 Hz, and the other side will be from 300 Hz to 2600 Hz. This will result in one side sounding 'bassy' or muffled, and the other side will sound 'bright' or hissy.

Before going after the filters make sure the carrier
oscillator is centered correctly. The book gives a method
where the residual carrier is made equal for both sidebands.
Actually its looking at the upper skirt of one filter and
the lower skirt of the other filter. It might be
interesting to vary the carrier oscillator a little while
listening to a comparison of the sidebands to see if the
audio response can be made the same on both. It may be that
one filter has somewhat different pass band response than
the other. If considerable it means one filter is bad. Go
over this adjustment procedure again very carefully. It
can't hurt and you may discover the filters are OK.

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

18033. Drake Technical Net Time Change

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-01-06 14:09:08 UTC
From: Mark Gilger
Topic: 18033 Message: 18033

Since the 40 meter technical net was created many years ago, the Sunday start time has always 20:00 GMT . Due to recent problems with broadcast station interference, we have decided to move the net to a new time of 4 pm Eastern. This will take effect this coming Sunday, January 12th.

Moving the net has been a regular discussion point every winter for several years now, but no action was ever taken. This year the signal strength of the interfering station has been so strong, we felt it was needed to keep the net healthy. Please make the new times on your calendar and we hope to hear everyone this coming Sunday at the new time.

The Tuesday evening net remains unchanged and will remain on Tuesday at 8:00 PM on 3.865 mhz.

Sunday @ 4:00 PM Eastern on 7.238 mhz +/- QRM

From: Dan Galligan
Topic: 18034 Message: 18034

Got an email, an hour or so ago, from R&L Electronics, with the following Drake equipment for sale, so, I thought I ought to pass it on to y'all.

DRAKE
P75 HYBRID PHONE PATCH $49.00
TR7 DC CABLE 12V DC APROX 6FT $34.00
DC4 DRAKE DC4 MOBILE POWER SUPPLY $59.00
TR4C AM/SSB/CW 80 THROUGH 10 TRANSCEIVER 15M AND 10 METERS VERY LOW OUTPUT $325.00
RT4524 Remote Control for Satellite $10.00
TR4C AM/SSB/CW 80 THROUGH 10 TRANSCEIVER AM/SSB/CW 80 THROUGH 10 TRANSCEIVER $350.00
L7 160-15 METER 1KW AMP 160-15 METER 1KW AMP $1495.00
MS4 DRAKE EXTERNAL SPEAKER NO FEET ON THE BACK $69.00

73,
Dan

18035. RV7 Stiff PTO

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-01-06 21:14:28 UTC
From: Don Cunningham
Topic: 18035 Message: 18035

Anyone out there dealt with a "stiff" PTO on an RV7 successfully and easily?? I have a friend, not on the list, that has just bought an RV7 to go with a TR7 he got from me in a trade and he finds the RV7 PTO very stiff. I think the PTO on the late serial numbered TR7 was "silky" enogh that it spoiled him, hi, and i realize that most RV7's weren't used very much but thought I'd see if any of you had any ideas I hadn't thought of. I suggested letting some light machine oil (3 in 1 or similar) run down the shaft from the front while working the shaft, but didn't want to suggest anything more drastic till I asked the "guru's".

Don, Its a standard PTO and as I look at mine (which is not tight) it has
the allen wrench hole, the tool if I recall is a deep 3/32'nd. Carl WD8NHK

A single drop of oil, and no more, on the ball bearings may do it. Nylon gears should have no lube on them or they can swell up and bind. This is a well documented problem, although I do have a late R-7A that looks like it has factory lube on the gears with no problems (and is silky).

Otherwise, my process is to tear down, clean, and lube the mating metal parts and ball bearings (if necessary) with TriFlow clear bicycle grease. Not exactly a quick or casual fix.

Adjusting the tesion on the bearings has been documented a number of places, but I've not had to touch it in my gear.

Maybe.... My understanding is International is/was a 're-boxer'. They buy tubes wherever they can, then put their name on them.... No way to know who might have actually built the tube.

So they 'might' work, but the odds are against you.

Yes it is possible to identify the actual manufacturer. Send me or the list a good photo clearly showing where "6JB6" is printed on the tube

The brand on the box and stamped on the glass is nearly meaningless. There was so much cross branding, even amongst the big three. You will find GE tubes marked as RCA, Sylvania marked as GE, etc. Let alone once you get into the privately labeled stuff. You need to look at the physical construction and how the _manufacturer_ marked the tube before it was branded. Again, pictures often tell the tale.

Chris -

I know Sylvania had an exclusive deal with Zenith to make Zenith branded tubes, but my understanding from someone who
worked at Sylvania was that they never cross-branded tubes from anyone else.
They sold to others but if it said Sylvania on it, they made it. They had Yellow branded tubes that were for
Distributor sales, and Green were sold in bulk only to OEMs, with a reduced warranty.

I worked for a big distributor in Louisville while I was in High School, and my fondest memory is of the 60' long, floor
to 7' high, double sided aisle with all those beautiful yellow and black boxes!!!.. I still recall the 12AX7 sold for
$0.93.

18049. L4-B and 3-500Z

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-01-08 02:31:16 UTC
From: Ryan Scott
Topic: 18049 Message: 18049

Greetings to the group. About a year ago, I picked up a L4B an PS from a local craigslist ad. Looked decent and complete, but had no way to test, but ended up picking it up anyway for $500. I ended up picking up the Harbach PCB and kit to rebuild the PS (which had original caps). I also have the soft key which I have yet to install. Once I rebuilt the PS and tested it with low voltage, I applied AC power (I wired it for 120 since I don't have 220 readily available) and POP went the .82 ohm resistor. Double checking my work (interlock disabled and well aware of HV danger!) after waiting for the PS to discharge I checked the plates of the tubes to ground and had no continuity. So it appeared nothing was shorted on the HV line. I pulled both tubes out, and fired it up after replacing the .82 ohm resistor in the PS. No pop and plate voltage indicated on the meter and confirmed with my Fluke DMM with HV probe. Put in the 'newer' looking
tube only (they did not appear to be matched) and again applied power. POP again. Another 0.82 ohm resistor, pulled that tube out, put the other tube in, apply power, all OK. (filament and bias cut off voltage appear normal - no RF applied yet).

At this point I am trying to decide if I should continue with the amp as I already have $650 invested in it and I may need to put another $400 into it. (tubes and plate tuning capacitor)

My questions for the group are:

1) Plate tuning cap has arcing right under where the tank coil connects to the cap on top. (previous owner filed down, but about 1/4" of plate is missing and somewhat pitted). Assuming that the previous owner overdrove this amp to cause this or something else?
2) Aside from another parts unit, where would one obtain this plate cap, or can it be repaired?
3) Can I test the amp with the one tube in it? if so, what would the recommended drive levels and plate/grid current be?
4) I cannot find any visible damage on the tube that is bad and it checks OK with a DMM (no shorts) but when it's in the amp and HV is applied... POP!   --- Not wanting to get into a lengthy discussion on tube failures but what causes this? Is the plate coming into contact with the grids when HV is applied, or is the grid shorting to the cathode and turning the tube full on and causing the overload at power on?

I'm usually a lurker on the group and appreciate all the discussions. This has been keeping me up at night and I thought I would see what the groups collective wisdom brings me.

73, Ryan N7QJ

I have seen 3-500Z's fail in the same manner. Always assumed grid to plate short since the grid chokes would pop. Heating would cause them to touch but that was just a WAG on my part.

The amp is worth the investment; you'd get your money back if you sold it.

I have no reason to disbelieve your claim being true during the time you worked there. However, I know for a fact that Zenith brand tubes exist that were not made by Sylvania. I have Zenith branded 6BQ5's that were made by Amperex, for example.

As for ALL Sylvania tubes being manufactured by Sylvania, this is a possibility. I can't think of a tube to dispute this with offhand. Out of sheer intrigue, I will rummage through some boxes and see if I can confirm this.

I'm not saying that the exclusive deal with Zenith didn't exist- only that it must have changed throughout the years, or with types of tubes (receiving versus power versus sweep, etc)

Also, it's not impossible under said Zenith contract, that Sylvania couldn't have subcontracted some tubes to other manufacturers that were tooled up to make a specific tube at that time.

That being said, All of the actual Sylvania branded 6JS6's I have seen thus far were indeed made by Sylvania.

I would still double check, regardless what brand they are inked. If manufacturer is unable to be determined, agreed sticking with the Sylvania name would yield better odds.

Regards,
Chris kc9ieq

Need a new drake dial?

Check this out. I have no ownership in this business but it might be a way to salvage some Drake rigs with bad dials. He says he needs a bad dial to use for a model.

Thank you, Dieter. Your AVR looks interesting. I have a sufficient supply of PROMs to last a little while, but other solutions will be needed when they are gone and supplies have dried up or gone crazy expensive.

Discussion is good. Everything surfaced that let this come together, and new ideas are afoot. Allons-y!

I have no reason to disbelieve your claim being true during the time you worked there. However, I know for a fact that Zenith brand tubes exist that were not made by Sylvania. I have Zenith branded 6BQ5's that were made by Amperex, for example.

As for ALL Sylvania tubes being manufactured by Sylvania, this is a possibility. I can't think of a tube to dispute this with offhand. Out of sheer intrigue, I will rummage through some boxes and see if I can confirm this.

I'm not saying that the exclusive deal with Zenith didn't exist- only that it must have changed throughout the years, or with types of tubes (receiving versus power versus sweep, etc)

Also, it's not impossible under said Zenith contract, that Sylvania couldn't have subcontracted some tubes to other manufacturers that were tooled up to make a specific tube at that time.

That being said, All of the actual Sylvania branded 6JS6's I have seen thus far were indeed made by Sylvania.

I would still double check, regardless what brand they are inked. If manufacturer is unable to be determined, agreed sticking with the Sylvania name would yield better odds.

Regards,
Chris kc9ieq

` Probably someone on the Tube Collectors list would know for certain. I do know that Sylvania had a lot of trouble with RCA over patent rights partly because RCA thought they were making better tubes. At some point in their history RCA, GE and Westinghouse may have sold tubes under their brand names made by the others but I think Sylvania was out of this. A look at the structure of the 6JB6 shows a lot of variation among brands. I have a box full of them, some good some not, as spares and will have a look. Of all the makers Sylvania seems to have been the only

one to include information on the use of the 6JB6 as an RF
amplifier, the others just show it as a sweep tube.
A lot of the puzzles about tube manufacturing traces
back to the intrigue and incest surrounding the formation of
RCA and its evolution into a monopoly of manufacture.

Well I just did some quick digging and spot checked a bunch of Sylvania tubes.

I am sorry to say that across the board, a Sylvania branded tube is not necessarily manufactured by Sylvania. I have in front of me a NOS Sylvania 6S4A, which is actually made by RCA. Also a much older (leaf logo on base) 6H6GT/G which was also made by RCA, but branded Sylvania.

Also, I found a NOS Zenith 6ME8 which was made by GE- not Sylvania.

<insert sad trombone sound>

So against hope, looks like we still have to look beyond the cardboard and ink.

18057. RE: [DrakeRadio] L4-B and 3-500Z

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-01-08 12:27:33 UTC
From: keith evans
Topic: 18049 Message: 18057

Hello Ryan,

It maybe that the L4B has not been fired up for a considerable time.

And it maybe the suspect tube has become gassy.

However, first check around the Grid circuits to make sure they haven't been damaged.

Then you could try removing the HT and just leave the amp with the Heaters on for about 24hrs,

This hopefully will get the Getter hot to expel the air.

With a Variac, bring up the HT slowly over slowly over a period of time, until you get to the CW/ TUNE norm of about 1800v.

If all is well, Tune and Load up the Amp to the max CW/ Tune output, and leave it sit there for a 30secs to a minute to let the Tubes get good and hot,

This will hopefully get the Getter to remove any remaining air.

Don't keep it on TX so long that you damage the psu

Do this perhaps 5 or 6 times. With cooling down periods about 3 times longer than you had it on Tx,

If all is well try running the amp in the SSB position and hopefully it will be ok.

If it blows another Glitch resistor then the problem is likely to be the suspect tube.

I hope this makes sense.

Subject: [DrakeRadio] L4-B and 3-500Z

Greetings to the group. About a year ago, I picked up a L4B an PS from a local craigslist ad. Looked decent and complete, but had no way to test, but ended up picking it up anyway for $500. I ended up picking up the

Harbach PCB and kit to rebuild the PS (which had original caps). I also have the soft key which I have yet to install. Once I rebuilt the PS and tested it with low voltage, I applied AC power (I wired it for 120 since I don't have 220 readily available) and POP went the .82 ohm resistor. Double checking my work (interlock disabled and well aware of HV danger!) after waiting for the PS to discharge I checked the plates of the tubes to ground and had no continuity. So it appeared nothing was shorted on the HV line. I pulled both tubes out, and fired it up after replacing the .82 ohm resistor in the PS. No pop and plate voltage indicated on the meter and confirmed with my Fluke DMM with HV probe. Put in the 'newer' looking tube only (they did not appear to be matched) and again applied power. POP again. Another 0.82 ohm resistor, pulled that tube out, put the other tube in, apply power, all OK. (filament and bias cut off voltage appear normal - no RF applied yet).

At this point I am trying to decide if I should continue with the amp as I already have $650 invested in it and I may need to put another $400 into it. (tubes and plate tuning capacitor)

My questions for the group are:

1) Plate tuning cap has arcing right under where the tank coil connects to the cap on top. (previous owner filed down, but about 1/4" of plate is missing and somewhat pitted). Assuming that the previous owner overdrove this amp to cause this or something else?

2) Aside from another parts unit, where would one obtain this plate cap, or can it be repaired?

3) Can I test the amp with the one tube in it? if so, what would the recommended drive levels and plate/grid current be?

4) I cannot find any visible damage on the tube that is bad and it checks OK with a DMM (no shorts) but when it's in the amp and HV is applied... POP! --- Not wanting to get into a lengthy discussion on tube failures but what causes this? Is the plate coming into contact with the grids when HV is applied, or is the grid shorting to the cathode and turning the tube full on and causing the overload at power on?

I'm usually a lurker on the group and appreciate all the discussions. This has been keeping me up at night and I thought I would see what the groups collective wisdom brings me.

73, Ryan N7QJ

Ryan,

When you placed the tube in the socket that did not pop the glitch resistor, did you place it in the same socket that popped the glitch resistor?

Did you leave the HV line disconnected and attempt to power the amp on just to light the filaments? The filaments will not provide enough heat to anywhere begin to getter the tubes. If a DVMM shows infinity between the grids and plate, that doesn't mean much at high voltage. You may have a short that would only show up on high voltage. I imagine that you could megger the tubes, checking the "non popping one against the popping one." I would first ensure that you are placing the tubes in the same socket to ensure you don't have some failed component on the tube socket.

When you get the thing running, I would only apply a carrier for a short burst, nothing long and tune up as quickly as possible.

Do you know anyone close that has a known good set of tubes or an amp that you can test your tubes in?

I have heard of some that have run the amplifier with one tube. It will tune and load completely different than if two tubes were installed. I would think it a worthy experiment. I would first closely inspect the wiring and components around the tube sockets. If you have placed the suspected bad tube in the same socket every time, the socket, wiring and its components may very well be at issue rather than the tube.

Hopefully Evan will chime in shortly.

Ryan,

One other thing that would yield great information would be to post your question on eham in the amplifier section. W8JI, Tom Raunch, is a wealth of knowledge and has a great website w8ji.com. In addition I would also aim the question at Steve Katz, WB2WIK. He is another that builds repairs and is a significant resource on amplifiers. He has posted a number of articles in QRZ and has helped a tremendous number of hams with amplifier issues.

The holidays are over, it's time to start working on some radios - that is, when job and home improvements aren't eating into the time!

I've got two 2-B receivers that have been repaired, cleaned and aligned. They're ready for new homes.

#7979 is in average-to-above average cosmetic condition. The chassis has some bright spots but is mostly brown, like an old penny. Small rust spots but nothing bad. Lettering is worn around the POWER and CALIBRATOR switches but otherwise the front panel is in good shape.

#6237 is definitely above-average. Chassis is mostly bright copper, with no wear on the front panel.

Both receivers have been aligned and checked out. They have their original tubular capacitors and are not humming. Both have nice cabinets with little scratching, rubber feet intact and no dents. They both work as they should and are hot little receivers!

If desired, I will order and install a Hayseed or 2-B re-cap kit for an additional charge. Will ship overseas but I will declare a value on Customs forms.

I have pics available - please contact me off-list for pics, prices and shipping info.

Chris -

I know Sylvania had an exclusive deal with Zenith to make Zenith branded tubes, but my understanding from someone who
worked at Sylvania was that they never cross-branded tubes from anyone else.
They sold to others but if it said Sylvania on it, they made it. They had Yellow branded tubes that were for
Distributor sales, and Green were sold in bulk only to OEMs, with a reduced warranty.

I worked for a big distributor in Louisville while I was in High School, and my fondest memory is of the 60' long, floor
to 7' high, double sided aisle with all those beautiful yellow and black boxes!!!.. I still recall the 12AX7 sold for
$0.93.

Yep -

That sounds very much like a lot of SB-220's and the occasional TL-922 that I'd work on, back when I used to repair these amps for pay.

You could meter the tubes anywhere you wanted, on the 20M range - it didn't matter. They would show as open, you'd put them in the amp and one or both would make the grid chokes go "POW!".

The root cause could be sagging grid wires - possibly caused by over-driving/excessive grid current or from a previous parasitic oscillation. Evidence of a possible parasitic or other stress is evident from your description of the plate tuning cap as having an area that severely arced. A tube that exhibits such a short is now a shack decoration or lamp base, I'm afraid. It will never work again.

I know I'm going to get some flack for saying this, but if you put the grids at *almost* DC ground and at RF ground, by using a 30 ohm 1/2W MF resistor from each grid to the chassis, plus extra capacitance on each pin, you'll lose a few watts of output but will gain having a true 5c fuse in the grid that will open up with a mere wisp of smoke under a catastrophic failure such as a grid-to-plate short or parasitic oscillation. I fixed loads of Heathkit amps, plus some Ameritron and Kenwood amps using this circuit. Those grid chokes are a lot harder to get than a 5c resistor!

My Amp Supply LC-500ZB was changed over to this circuit and I was able to get over 1300W out with it on 20m and about 1100W on 10. I also had some different parasitic suppressors on it, which reduced the power out a little. Losing a couple hundred watts was a small price to pay to prevent parts inside from blowing up

Here's a shot of a grid-cathode short.

Chris -

OK. Now that I think about it, we were discussing sweep tubes at the time, and perhaps that was what was intended. I
know Sylvania was the only one to characterize their sweep tubes for RF service, and publish the results, at least at
that time. I never worried about typical receiving tubes, as they were usually used for their intended purpose and I
knew there was cross-branding among most all 'major' manufacturers.

My experience with sweep tubes has been that sticking with the 'big 3' plus Zenith gives a 100% success rate. Any other
brand is a crap shoot. Some work fine, others not so much!... I have also found that 6GJ5s are also 100% IF you stick
to the same brands. The only difference is that the Suppressor grid is tied internally to the Cathode, in the GJ,
rather than being brought to it's own pin. This does alter the neutralization a bit, but so far at least still within
range of the cap in the T-4X(any). I've not tried them in the TR-4(any) and so that might take a slight adjustment to
the neut cap.

The most interesting anomaly I have found is the VERY occasional 'too tall' 6JB6. I've never personally seen an RCA or
Sylvania oversize, but have heard they exist. They would have to be outside the maximum 'seated height' specified in
the data sheet for both brands.

Steve,

You have sparked interest on a project that I am working on. I have seen Evan make several comments about the grid resistors as you did. I am refurbishing an SB220 that I acquired about 10 years ago and had been forgotten in the shack's closet. Everything bad that could be done to an amplifier has been done to this one. ON top of everything else, it had been placed on 11M and all of the band components removed.

I have stripped it down to the bare chassis to repair metal damage where it was dropped on the side and produced a severe chassis bend. Inspecting the tube socket connections, reveals that at least one of the grid chokes is burnt open. I like the idea of replacing the chokes with resistors expressly because they are easier to source. Can you provide a little more information on replacing them with resistors and what capacitance you have added?

I'm rebuilding the power supply and meter board as a bunch of the components, traces etc are completely burnt due to "golden screw drivers" and cold or missing solder joints. This unit will be quite nice when done, but I want to make sure I do it right.

Thanks for your time,

Doug - N9XTF

Hi Jim -

Congratulations!! We've just GOT to win one occasionally!! :-)

I'd like to get one, 'just in case', cause I know that means I'll never need it!

I'm still stuck in Chicago, about a foot of snow, and it's up to almost 3 degrees already this morning..... Only going
down to -6 tonight, so that's a 10 degree improvement over the last couple of nights.

Definitely sounds like the tube is shorting to ground as HV is applied, you can run that amp with one tube and see if just the one tube is shorting, likely, but could be something wrong with the socket as well, unlikely, but worth checking. I have a couple of "good looking 3-500z" that are bad, same thing, short as I applied HV or shorted when pushing them just a little. Not worth the risk of blowing that Plate transformer up.. also you might switch the .82 ohm to a more recommended 10 ohm at 10 watts.. read the reseach on that..

good luck

Doug -

The change I did to the SB-220 was right out of AG6K's 1990 QST article. I used to get the kits from him and install them. Over the years, his findings have been controversial, but I will say that any amp that I put his mods into did not come back for a repeat repair.

Notwithstanding the efficacy of the parasitic choke changes, I did like his solution to the grid overcurrent issue. On the SB-220, this change involves a single 470 pf @ 1 kV disc ceramic cap at each of the three grid pins (thus adding about 1800 pf to the grid-to-chassis capacitance), plus substituting the 30 ohm, 1/2W flameproof metal film resistor for each grid RF choke.

Yes, this does change the bias a little compared with directly grounding the grid. It also means that you won't take out any transformers or other expensive components if and whan you get a grid short to either the plate or cathode.

Some of the photos I've seen show the cathode/filament actually either touching or being very close to the grid. On the SB-220, they use a centre tap from one of the transformers to supply bias to the tubes. If such a short occurred and didn't open up a cheaper component, it will take that transformer out. That, by itself, is reason enough for me to protect the $100+ part(s) by adding about a buck's worth of commonly-available components and accepting slightly-lower output as a trade-off. After all, 200W reduction from 1500W isn't even 1 dB (it's about 0.6 dB).

Good luck with your amp project! Chances are very good that only one tube is bad, and, if that is the case, I'd sell the good one at a "used" price and get a matched pair to replace both of them. There are even used matched pairs available out there, but I believe RF Parts has replacements at reasonable prices, new.

The good news is both tubes are good. I'm temporarily running them In my L4 in place of the 3-400z tubes. I alternate them to keep them de-gassed.

I've spoken to rich directly about a couple of other issues and sad some of his articles. I missed the one about the grid protection. I've also seen the garbage between the two.

Thanks so much for the info

Hi Group, here's a bit of an update on my amp. I got some time and pulled the Plate Tuning capacitor (that was a job) there were 2 plates top and bottom that were badly arced over and pitted. Luckily, I had another high voltage variable cap that came from a sputtering machine discarded from work that had a 1kW RF amp using a 3-1000. (I work in the semiconductor industry). I parted it out and kept most of the parts, one of the caps had the same construction and same plate dimensions. Anyway, I managed to replace the damaged plates on the capacitor and am putting it all back together. So that takes care of my first 2 questions from the original post.

Doug suggested I put the tube that seemed OK in the other socket. After checking the grid caps and RFC, I did that and applied HV, all was OK. That was a good suggestion that I did not think of, Thank you.

So now I need to re-install the cap, clean up, and find a pair of 3-500z's to bring this girl back to life.

So at this point, I'm wondering if anyone has tested an L4 with only one tube, or is this a bad idea?

Thanks,
Ryan N7QJ

On Wednesday, January 8, 2014 4:45 AM, "dcoffman@..." <dcoffman@pdswireless.com> wrote:

Ryan,

When you placed the tube in the socket that did not pop the glitch resistor, did you place it in the same socket that popped the glitch resistor?

Did you leave the HV line disconnected and attempt to power the amp on just to light the filaments? The filaments will not provide enough heat to anywhere begin to getter the tubes. If a DVMM shows infinity between the grids and plate, that doesn't mean much at high voltage. You may have a short that would only show up on high voltage. I imagine that you could megger the tubes, checking the "non popping one against the popping one." I would first ensure that you are placing the tubes in the same socket to ensure you don't have some failed component on the tube socket.

When you get the thing running, I would only apply a carrier for a short burst, nothing long and tune up as quickly as possible.

Do you know anyone close that has a known good set of tubes or an amp that you can test your tubes in?

I have heard of some that have run the amplifier with one tube. It will tune and load completely different than if two tubes were installed. I would think it a worthy experiment. I would first closely inspect the wiring and components around the tube sockets. If you have placed the suspected bad tube in the same socket every time, the socket, wiring and its components may very well be at issue rather than the tube.

Hopefully Evan will chime in shortly.

The only problems from running one tube are the filament voltage really goes a bit too high, the input SWR goes up, and it is easy to overdrive the amp.

If you don't run it too long that way and watch what you are doing, and don't let the unused anode cap hit anything, everything will be OK temporary. Just remember you are probably running up closer to 6 volts on the 5 volt filament of the single tube.

73 Tom

Ryan,

Ryan,

I have "tested" an L4B with just one tube on a couple of occasions over the years, as well as once with an L7, but not intentionally, hi hi. It happened due to desoldering of a filament lead in one instance and open filaments in the others. Interestingly, the amps did load up but capacitor settings were "off" and tuning was not as smooth. It was a lot easier to see a darkened tube with the L4B's perforated cabinet although I was given a hint with the L7 since it was on a shelf where I could see the glow from the tube(s) through the air inlet on the bottom. Amps basically worked, with reduced output, and on-the-air reports indicated things sounded fine. However, I would not recommend doing this intentionally except for very brief periods. Having a single tube failure, due to an open filament or desoldered filament pin, can be problematic if one tunes the amp for the typical output power, plate current, grid current, etc. since it will be the single operational tube that is taking an excessive load.

In addition to what has been said previously, there is a nit about running the L4/L4B with only one tube installed. With one socket empty, there might be slightly less air flow and cooling to the installed tube due to the lower back pressure from the socket lacking a tube, thus allowing the air to "find the path of least resistence". Not sure whether this is an issue or not, I lack a background in thermodynamics and dynamics of air flow.

As to the grid grounding RF chokes, they are indeed difficult to find. My supply is almost diminished and what I generally do as an alternative to replacing those chokes (due to a short to ground situation) is that I remove each of the grid chokes. Then, I install a 33 ohm 1/2 watt carbon resistor from each grid pin to ground. I leave the mica/disc capacitors in place. This results in using slightly lower driving power for a given value of grid current and it still enables some degree of protection, in addition to the 0.82 ohm safety resistor in the power supply, should there be a plate to grid short. Many designs, including those from Eimac, show the grids being grounded directly; this further reduces drive power needed but I like a little extra safety measure so I don't ground the grids directly.

Please keep us informed so we all can learn.

73,

Evan, K9SQG

Subject: Re: [DrakeRadio] L4-B and 3-500Z

Hi Group, here's a bit of an update on my amp. I got some time and pulled the Plate Tuning capacitor (that was a job) there were 2 plates top and bottom that were badly arced over and pitted. Luckily, I had another high voltage variable cap that came from a sputtering

machine discarded from work that had a 1kW RF amp using a 3-1000. (I work in the semiconductor industry). I parted it out and kept most of the parts, one of the caps had the same construction and same plate dimensions. Anyway, I managed to replace the damaged plates on the capacitor and am putting it all back together. So that takes care of my first 2 questions from the original post.

Doug suggested I put the tube that seemed OK in the other socket. After checking the grid caps and RFC, I did that and applied HV, all was OK. That was a good suggestion that I did not think of, Thank you.

So now I need to re-install the cap, clean up, and find a pair of 3-500z's to bring this girl back to life.

So at this point, I'm wondering if anyone has tested an L4 with only one tube, or is this a bad idea?

Thanks,
Ryan N7QJ

On Wednesday, January 8, 2014 4:45 AM, "dcof fman@..." <dcoffman@...> wrote:

Ryan,

When you placed the tube in the socket that did not pop the glitch resistor, did you place it in the same socket that popped the glitch resistor?

Did you leave the HV line disconnected and attempt to power the amp on just to light the filaments? The filaments will not provide enough heat to anywhere begin to getter the tubes. If a DVMM shows infinity between the grids and plate, that doesn't mean much at high voltage. You may have a short that would only show up on high voltage. I imagine that you could megger the tubes, checking the "non popping one against the popping one." I would first ensure that you are placing the tubes in the same socket to ensure you don't have some failed component on the tube socket.

When you get the thing running, I would only apply a carrier for a short burst, nothing long and tune up as quickly as possible.

Do you know anyone close that has a known good set of tubes or an amp that you can test your tubes in?

I have heard of some that have run the amplifier with one tube. It will tune and load completely different than if two tubes were installed. I would think it a worthy experiment. I would first closely inspect the wiring and components around the tube sockets. If you have placed the suspected bad tube in the same socket every time, the socket, wiring and its components may very well be at issue rather than the tube.

Hopefully Evan will chime in shortly.

Hello Group,

I reciently put my T4XC and R4C back on the air after being off the air for a bit. They are early serial numbers. The original finals were still in the T4XC, and were just a little weak. So purchased a pair of matched GE 6JB6's from RF parts. They neutrialized very well with no padding. Well after about a couple of times on the air, one of them must have had a grid problem. The one tube blew up the grid resistor, and the 650VDC AC3 diodes. RF parts was great, and did a RMA on both tubes, and sent me a new matched pair. I guess after 40-50 years sitting in a box they do have problems. Good news, it only took a few bucks to get the T4XC going again. This is the only problem it has had since 1973 or so.

Regards,
Ed WA6WGS

Yeah, I figured you would want one. :)

People have been coming out of the woodwork wanting these. I need to get shipping supplies and figure out cost after the dust settles down. I'll let you know. I'm selling these way too cheap, my cost works out to under 3 bucks (plus shipping, whatever that will be) per chip including the socket.

I'm guessing that you don't want a socket?

How do you program these chips? I can't find much information about it.
Last week I had to program a 27c256, and found that my 3 year old USB
programmer did not work under 64 bit (which I upgraded to a few months
ago) Windows 7.

The company's website keeps changing names and currently seems to be gone.

Having seen your postings, I figured since I was looking at new burners,
I should buy one that would program them too. The cheapest one I could
find was $750, and that came from the same company as the one I already
had. There was one which people say is well supported, but that one
costs $1500.

All of these prices don't include postage, and in my case, 18% VAT.

In the end, I needed to make a decision and just bought another $50
Chinese programmer from eBay. It does thousands of different chips, but
not these and my needs basically are 27xxx and 27Cxxx chips.

TIA and 73,

Geoff.

Jeff,

Well, this is not a "new" burner. It is a vintage MCT MOD-EMUP. It does EPROMs, PAL, GAL, bipolar PROMs, and who knows what else, as well as has the ability to test a variety of the CMOS and TTL logic chips of the day. A version was sold in Europe as the "Hi-Lo System" model ALL-03. You could probably find one if you look around. BUT... It requires a proprietary parallel interface card and an old ISA bus computer. I see the MCT box for sale on eBay now and then, but without the interface card it is useless. You may be able to build an interface card from info at http://matthieu.benoit.free.fr/120.htm . The computer also needs to have a standard-speed (not overclocked) ISA bus - one of my former employers tried to run one of these in a fast bus computer and damaged the interface card. I am running mine in the docking station for an old Compaq LTE Lite 4/25C laptop under PC-DOS 7.1. My previous workhorse was an MCT MOD-MEP, which used the same interface card but only handled EPROMs. It was a very reliable box.

You may be able to find something else by looking around the surpuls market or auction sites. Not much call for EPROM burners these days. Just be aware that a lot of them did use proprietary interface cards which frequently went away with the computer they were in, and there is also the issue of software availability. I was fortunate in that the MCT/HiLo programmers seem to have a following and the software plus a lot of other info is archived on the internet.

If you are "stuck" on Windows 7, you are probably alos confined to the high priced market. With older computers being practiaclly throwaway items, at least here in the USA, maintaining a second box with an older operating system for "obsolete" chip programming is the most practical solution.

You should see what I use to program GE Phoenix radios.

Thanks, I had something like that and sold it in 1996 when I left the US. I had no clue that almost 20 years later I would need it. It had a ISA interface card, and an external box with a chip socket. In those days it was used to make SUN CDROM drives out of Sony, and updating firmware in modems. I also did some ROMs for a local Motorola dealer, but I never knew what they went into, he just gave me the files and the chips.

As for old computers, the 27cxxx series ROMs I burn are used in old Motorola radios, so I am no stranger to old computers.

Most of what I use for programing the radios are Pentium 200 or similar processors, as that is what works, and the laptops of that era had active displays instead of slow passive LCDs. I have figured out how to run DOS 6.2.2, DOS 7/Windows 95/98 and on the later ones Windows XP. I have sitting on a shelf two Acer 486/66 computers, just in case I need something really slow.

You never know, one of these things may pop up. :-)

Geoff.

Indeed, you are. Remember your time and effort also have value.
No reasonable person is going to hold a reasonable price against you.
As a "rule of thumb," if you aren't at least doubling your
cash outlay on lower-priced items like these, you're actually
losing on the deal. Another "rule" is that only about 7 of 10
who say they will buy one will actually do so.
I'd pay double your costs and more and count myself very lucky
that someone like you took the risk to invest his
time and capital to address this issue. Thank you!

18091. RE: TR-4C 6JB6 Tubes

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-01-10 12:57:37 UTC
From: <w5rkl@...>
Topic: 18076 Message: 18091

Joe,

Also check the 3 individual 6JB6 cathode resistors (3 x 15 ohms 1 watt), meter resistors R13 (usually mounted on the PUSH/PULL meter switch, and the parallel resistor R45 (R45 may be shown as 2 ohms on the schematic).

I recommend using ceramic resistors for the cathode resistors. Mouser sells them under Mouser part number 588-OX-15-E for 92 cents each (15 ohm 1 watt 10%). For best results the cathode resistors should be as close to 15 ohms each as possible.

I also recommend using matched 6JB6s, as mentioned by a responder. Matched pairs of 6JB6s are available at RF Parts.

After replacing the final tubes and cathode resistors you should check the final amplifier's neutralization. If you need to neutralize the final, start on 20 meters first. The plate DIP is much more pronounced on 20 then it is on 10. Once you successfully neutralized the finals on 20 meters, move to 10 meters at 28.8. It should only take a very "slight", emphasis on "slight", tweaking of the neutralizing capacitor on 10 meter to complete the neutralizing task on 10. It's very easy to adjust the neutralizing cap past the "sweet spot" on 10. If you adjust the neutralizing cap too far on 10, start over on 20 and repeat the process.

Also, be very careful, the neutralizing cap screw adjustment has HV on it. Do not allow the screw driver to short the neutralizing cap adjusting screw to the chassis. Use an insulated screw driver to make the adjustment. If you don't have an insulated screw driver, wrap the shaft of the screw driver you plan on using with electrical tape, leaving only the flat blade portion of the screw driver exposed. I use a thin eighth inch wide flat blade screw driver with the shaft covered with electrical tape. The eighth inch wide thin flat blade screw driver is just the right size to fit the neutralizing capacitors screw slot.

The manual says to use the "PUSH/PULL" meter button to monitor RF output during the neutralizing process. I found using an external watt meter much easier (I used a Heathkit HM-102) as it allows you to see both RF output and the PLATE current meter (cathode current) indications at the same time.

Joe,

I forgot the mention you should use a 50 ohm dummy load when neutralizing the final amplifier. The dummy load should have a power rating higher than the TR4's maximum output power. I use a Vectronics VEC-552, 1.5KW dry dummy load. If you don't have a dummy load, MFJ sells a nice 1.5KW dry dummy load, MFJ-264, which has a 150 watts constant key down time of 60 seconds. There is a cool down period that should be followed. For example, at 60 seconds with 150 watts applied to the dummy load, the cool down period is 10 to 20 times the maximum rated key down period, i.e., 10 x 60 = 600 or 10 minutes. If you keep key down periods to less than half the rated period then cool down periods would be less. I found 10 seconds is more than enough time to make the neutralizing adjustments.

And, if you have a scope and are adept at desoldering, you can neutralize the amp very quickly. It involves tuning for a dip in plate current, disconnecting the screen supply (with power off, first, of course!), applying just enough drive to see RF on the scope at 28.8 and tweaking the cap for a null. Just be careful of desoldering and re-soldering that screen lead at the feed-through.

One adjustment, no trial and error. Robert's your mum's brother.

A good way to make a neutralizing tool is to grind
or file a screw driver tip on a length of plastic rod.
Suitable rod can be gotten from stores that sell plastic
goods, maybe even hobby shops. The tool will also tend to
introduce less stray capacitance. Do NOT use modern
adjusting tools because the plastic in most has been made
conductive to prevent static build-up. The resistance is
fairly high but I've gotten shocks from these tools even
with lower voltage than appears on the plates of the tubes.
The method I use on my T4XB and TR-4 is a slight
variation of the handbook method: I find the approximate
neutralization setting on 20 meters. Then go to 10 meters
and tune up with low drive and careful tuning. The reason
for neutralizing on the lower band first is to avoid getting
a combination of plate tuning and loading settings which
cause the finals to oscillate. Once I find the correct
setting at 10 meters I alternate the tuning, load and
neutralizing adjustment for maximum output. That gets the
neutralizing adjustment right on the money. I agree than an
external power meter is, if not absolutely necessary, a
great convenience.
I am not sure what is being matched with matched
tubes. I think the main thing for parallel operation is to
make sure both tubes draw about the same amount of current.
I made an adaptor for my TV-7 tube tester to take
compactrons and check the finals for Gm. This seems to work

and agree closely with measured cathode current. I also found that the Gm of unused tubes of the same brand seem to match pretty closely so I am not at all sure how necessary it is to pay a substantial premium for "matched" sets. The other thing is that one presumably wants tubes with similar interelectrode capacitances. Not sure how much variation there is in production tubes although different brands with different structures may vary. This can be measured but needs special instrumentation like a General Radio vacuum tube bridge. If a set of tubes neutralizes OK all this is just of academic interest.

18096. Drake radio items for sale excess to my needs

Note, this may be a repost; I posted this morning but it has not shown up on the Yahoo Group.

I have the following Drake items for sale as they are excess to my needs;

1 ea Drake TR-4. Fully aligned, new finals, new power switch installed on the AF/RF gain pot, new Ohmite screen and grid resistors, installed TR-4C audio board, new multi-section Hayseed Hams capacitor installed. The front panel is very nice, the case could use new paint and the top of the chassis is rough; it needs a good cleaning and has pitting.

2 ea Drake AC-3 power supplies. They both work but should be re-capped. One of the units someone replaced one of the caps with an axial lead cap and the cover and strain relief is missing from the multi-conductor plug.

Contact me off the list at dcoffman@pdswireless mailto:dcoffman@pdswireless if interested.

Regards,

Doug - N9XTF

I have the following Drake gear for sale that is excess to my needs;

2 ea AC-3 Power Supplies. Both work however recapping is suggested. Someone has replaced one of the caps with an axial lead unit.

1 ea TR-4 fully aligned with new final tubes. Power switch has been replaced with a new switch on the back of the AF, RF gain pot. Grid and Screen Resistors have been replaced with Ohmite OX OY versions. The multi section cap has been replaced with Hayseed Hamfest's cap. The face is very nice but the cabinet could use a new paint job. The top of the chassis needs to be cleaned and is fairly rough.

Contact me off the list if interested at dcoffman@pdswireless.com

Been lurking for awhile, and thought I'd join. Been around as a ham for about 20 years, and have had a few Drake sets over the years. Presently enjoying a Drake SW-4A that suits my needs. I have a couple questions. This set has not been recapped. It is a later production serial number, probably around 1973. I don't detect any serious hum or issues. What is the general consensus regarding caps on these sets? Replace as a matter of preventive maintenance, or repair as needed? Also hoping that someone out there may have an excess MS-4 speaker that they would be willing to sell. Can't seem to find one up here in Canada yet, and the EBAY ones seem complicated to obtain with Global Shipping Program issues an the like.

Thanks,

Chris -

First of all, welcome to our family!

My philosophy is that, if you're using the receiver fairly regularly, to not worry about the caps. There were solid-state diodes used after the transformer. Therefore, if you're not hearing excessive hum now and the cap was going to fail, the diodes would fail in an overcurrent situation.

Having said that, it's good PM to replace the caps when you get a chance. There are a number of providers of original-style replacements, which would afford you a minimum number of changes. Hayseed Hamfest is one, and 2B radio parts is another. You can also always go about it freestyle and sneak new caps under the chassis. Just be certain that you have disconnected the original ones, first.

Thanks for the welcome Steve. I'll likely just use the set for now, and keep an eye (or ear) on things. Seems like the cap kits available are oriented to the 2 and 4 line amateur rigs. The SW-4A uses a different cap configuration, but it shouldn't be difficult to recap under the chassis. I've done a few sets that way, most notably a German hifi set recently that was a bit of challenge, so I don't expect the Drake to be too bad. And to Billy - thanks for the offer on the complete station, but I'm just looking for an MS-4 speaker for my receiver at this time.

Hayseed Hamfest will make a cap for you to fit in your radio. I have used them and they are nice replacement caps. I have also re-stuffed old can caps too. Cost is much less but it takes time. (Cut the can open at the flair with a hack saw or a Dremmel Tool, if you have one, gu t the old caps out, replace with new radial lead caps, place cover back on the cap base, tack with 5 min epoxy in three places. When firm, run a bead of aluminum colored silicon rubber over the concave flair and then wipe a nice concave flair with your finger. DONE!) . The finished product will look near perfect and the cost will be around $7.00. As I sa id, Hayseed Hamfest is good too. In fact I had them ship me a couple TR-4 caps today. They do all the work for you!

I've worked on an SW-4 in the past. Given that they were produced concurrently with the 4-Line, there may well be a replacement available. I would first look at the equivalency of the SW-4 to the R-4A. That was a 4-unit cap.

Check with Hayseed Hamfest. If it's not equivalent to any of the other 4-line, it's probably close.

Subject: Re: [DrakeRadio] New to Group

Thanks for the welcome Steve. I'll likely just use the set for now, and keep an eye (or ear) on things. Seems like the cap kits available are oriented to the 2 and 4 line amateur rigs. The SW-4A uses a different cap configuration, but it shouldn't be difficult to recap under the chassis. I've done a few sets that way, most notably a German hifi set recently that was a bit of challenge, so I don't expect the Drake to be too bad. And to Billy - thanks for the offer on the complete station, but I'm just looking for an MS-4 speaker for my receiver at this time.

Thanks for the comments, Dave. The price will go up. The introductory low price was my way of giving back to this group and the people on it who are so helpful to myself and others. I had planned on a higher price once I get these folks taken care of. This is a private offer to this list, and I will cut it off soon.

I have a couple questions. This set has not been recapped. It is a later production serial number, probably around 1973. I don't detect any serious hum or issues. What is the general consensus regarding caps on these sets? Replace as a matter of preventive maintenance, or repair as needed? Also hoping that someone out there may have an excess MS-4 speaker that they would be willing to sell. Can't seem to find one up here in Canada yet, and the EBAY ones seem complicated to obtain with Global Shipping Program issues an the like.

Chris -

First of all, welcome to our family!

My philosophy is that, if you're using the receiver fairly regularly, to not worry about the caps. There were solid-state diodes used after the transformer. Therefore, if you're not hearing excessive hum now and the cap was going to fail, the diodes would fail in an overcurrent situation.

Having said that, it's good PM to replace the caps when you get a chance. There are a number of providers of original-style replacements, which would afford you a minimum number of changes. Hayseed Hamfest is one, and 2B radio parts is another. You can also always go about it freestyle and sneak new caps under the chassis. Just be certain that you have disconnected the original ones, first.

HTH,

Steve Wedge, W1ES/4

I don't know about the short wave receiver but the caps in my R4 and T4 are film caps or ceramics, not paper. I did have to replace a couple of electrolytics but neither plastic film or ceramic caps go bad with age the way paper caps do. The limited life of paper caps was well known when they were new, many engineering books will have derating data on cap lifetime. The higher the cap voltage rating in comparison to the voltage on it the longer they would last. In any case, Drake stuff does not seem to require the kind of shotgunning of all caps they way older equipment does.

R.I.P. Jack. Truly one of Amateur Radio's GIANTS...

"Boy! Love them smooth rippling dits. Wow!"

73, Garey - K4OAH
Glen Allen, VA

<<<<

"John G. Troster, W6ISQ, became a Silent Key on January 11, 2014. His wife of 65 years, Marguerite (KC6NFE), was at
his bedside when he passed away.
Jack, along with Vince Chinn K6KQN (now W6EE), Lee Shaklee W6BH (SK), and Don Schliesser K6RV, founded the Northern
California DX Foundation in October, 1972. Jack served as an NCDXF Board member for 26 years before stepping down
in July, 1998. He was the Foundation’s third President, serving from 1975 until 1986.
Jack had an enormous passion for amateur radio. He was first licensed in September, 1935, at age 14, as W2ISQ in
Yonkers , New York . He received his W6ISQ callsign when he moved to California shortly after the end of World War
II. Among Jack’s many radio accomplishments and awards were DXCC #1 Honor Roll on the Mixed, CW and SSB modes;
5B-DXCC; 5B-WAS (Certificate #4); and USA Counties Award (for working all 3,076 USA counties, which he did
completely on CW!). Jack was a member of the FOC and the A1 Operators Club; he served as president of both the
Northern California DX Club and the Northern California Contest Club; he was a Contributing Editor of QST magazine
and was the Pacific Division’s representative on the ARRL DX Advisory Committee. He was a director of the Quarter
Century Wireless Association and for years wrote the monthly QCWA column published in World Radio News. Jack was
named NCDXC’s DXer of the Year, and in 1988 he was inducted as the 27^th member of the CQ DX Hall of Fame.
As impressive as were all his radio achievements, even more so was Jack himself. He was the consummate gentleman.
He was warm and welcoming to everyone he met, and many amateur radio operators today enjoy the hobby as a direct
result of his nurturing, encouragement and enthusiasm. Jack was known for his quick wit and encyclopedic knowledge
of amateur radio history. His passing leaves a huge void. Amateur radio has lost one of its giants."

Hi Al -

No, that was Phil Gildersleeve 'Gil', W1CJD. Most of Jack's stories had a 'Gil' cartoon included. Gil started as a
'filler' in QST. Someone would give him a brief 'idea' and he'd come back with an appropriate cartoon reflecting that
idea. Jeeves was associated with the DX Column run for so many years by Byron Goodman, W1DX.

18117. FS: Unique Drake Service Supplement CDs

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-01-14 17:38:54 UTC
From: Garey Barrell
Topic: 993 Message: 18117

Here is the information that Drake left out of their manuals!

Unique supplemental service information CDs available for the Drake A, B and C Lines, 2-B, 2-C / 2-NT, TR-4, and
TR-4C/Cw/CwRIT.

High resolution color photos of the under chassis and individual PC boards of each unit, with all parts identified and
keyed to a parts list make it easy to locate any component. No more trying to trace wires through bundles, etc. This
information is not available elsewhere and really makes a difference in servicing these units.

These CDs are not JUST scans of the original manuals that were included with the equipment when new. High resolution
scans of the original manuals ARE on the CDs, along with scans of manuals for associated equipment such as the C-4,
FS-4, MN2000, L-4B, W-4, etc.

Samples of these pages (at reduced resolution) and purchase information are at <www.k4oah.com>.

With deep sadness, I think, I am going to put my L4B up for sale. I lusted for one, for more than 35 years, since I saw my first, sitting alongside an ETO Alpha 77DX. Now, I have an Alpha, and the L4B is truly excess to my needs.
It has been in storage, 3 years, since I last fired her up. So, I am not "officially" going to sell it, until I hook it up, and test it, so that I can verify that it works as good as it looks. Once I have verified that, I will post photos, in the photos section. It will include 3 additional 3-500Z's. One N.O.S. Eimac, and two "other" used, that test as full output. The L4B is in excellent physical condition, with the original power supply. If, for some unexpected reason, it does not test well, it will NOT go up for sale, until it is working properly. Currently, I am floating a "trial balloon" as they say in the world of politics, to see if there is interest.
I will work with the buyer, and deliver, within a reasonable distance, of Vian, OK. I am NOT going to set a specific travel limit, but, we can discuss a fair and equitable manner of getting it to the buyer. Obviously, shipping, due to the weight of the P.S., will be pricey, if shipping is necessary.
For all of this, if it goes as planned, I expect to ask $1200 obo.
I expect to have it connected and tested, by this Friday, January 17, 2014.
Please email me, off list, if you are interested.
Also, the new year, greeted me, with sharply reduced income, and most of the radios I am not truly married to, will likely be going up for sale. I may be putting both my "B" & "C" Twins, up for sale, in the near future, as well as some other boatanchors. Tune in for more info.

Always good to bring up an amp slowly with a
Variac/Powerstat when it has been sitting a while...

I really think this is just fooling yourself. If you
think the power supply filter caps might be bad they can be
checked without powering up the supply. If the amplifier
has not been used for several years its a good idea to run
the finals with filament only for a couple of days. That
will help getter any gas that may have accumulated. If you
can bring the high voltage to the tubes up gradually and
watch for signs of gas or arc-overs its a good idea but not
possible on most small amplifiers. Once the amp is up,
assuming the tubes don't arc or show signs of serious gas
(glow discharge inside like a gas rectifier tube) run them
into a dummy load at red heat for a while. This should not
hurt the tubes and will getter any gas inside. Power tubes
do not do will when stored. According to Eimac the longest
tube life is gotten in continuous service.

Hopefully, I'm not fooling myself but I'm not the sharpest knife in the drawer so it is easy to be deceived. What I have done in the past, which has worked successfully for me (your mileage might vary) is to bring up an amp slowly with "my" Variac. The one that I have has a voltmeter, ammeter, and wattmeter. As I bring up the voltage slowly, I watch the ammeter and wattmeter. If the current rises at almost the same rate as the voltage, I power things down and look inside the amp and power supply. This procedure has enabled me to find questionable electrolytics, disc ceramic line bypass caps that had excessive leakage, highly gassy 3-500Z tubes that had a beautiful purple glow (pre-flashover, hi hi), and so forth.

Always good to bring up an amp slowly with a
Variac/Powerstat when it has been sitting a while...

I really think this is just fooling yourself. If you
think the power supply filter caps might be bad they can be
checked without powering up the supply. If the amplifier
has not been used for several years its a good idea to run
the finals with filament only for a couple of days. That
will help getter any gas that may have accumulated. If you
can bring the high voltage to the tubes up gradually and
watch for signs of gas or arc-overs its a good idea but not
possible on most small amplifiers. Once the amp is up,
assuming the tubes don't arc or show signs of serious gas
(glow discharge inside like a gas rectifier tube) run them
into a dummy load at red heat for a while. This should not
hurt the tubes and will getter any gas inside. Power tubes
do not do will when stored. According to Eimac the longest
tube life is gotten in continuous service.

18128. R-4A HUM!

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-01-15 18:49:18 UTC
From: K5MYJ
Topic: 18128 Message: 18128

This morning I tried setting up my R-4A to monitor on of the AM frequencies.

When I switched it from SSB to AM I got a lot of 60Hz(120Hz?) hum. I get no hum in either CW or SSB.

I would think if it was a power supply capacitor it would have hum in any mode.

I need to find time to put it on the bench and use the scope on it.

A metered Variac is something else and I think a good idea. You can tell right away if something is drawing too much current and shut it down. What I was objecting to is the idea of bringing voltage up slowly over hours with the idea that it will somehow allow bad caps to reform etc. I used this method routinely at -hp- where the Variac was also used to check the regulation of regulated power supplies. If you don't have a metered Variac the old trick of a light bulb in series with the equipment will help since it will also give some indication of sudden high current draw and to some extend limit it.

18130. Re: [DrakeRadio] RV-4C NOT WORKING

Yahoo group: DrakeRadio (2014-01 — 2014-05)

From: Garey Barrell
Topic: 18120 Message: 18130

Doug -

The 'early' version of the RV-4C used a 2W resistor. The 'late' version specified the 5-1/4W wirewound. The resistor
dissipates 1.92 W, when the unit is OFF, or 1.7 W when it is ON in any mode. Essentially if the red light is OFF, R15
is dissipating 1.92 W.

Obviously, a 10W wirewound is fine. A pair of 30K, 2W resistors in parallel would be ok too.

Yup, works fine. See attached

The TR-4 CD has a 'TR-3 Supplement' that includes all three schematic versions. Some of the photos are pertinent, and
there are some additional documents. The TR-3 isn't all that different than the first TR-4 version.

You are probably close to one or more fluorescent lighting fixtures. Ground loops can also do this in AM mode.

The key to this is that you hear the hum only in AM. If it was the filter caps, you'd hear hum in all modes.

Try reversing the AC line cord first, then try grounding the chassis in addition to whatever it's getting via the coaxial lead. If still no joy, cut off other circuits in your house and see if the noise goes away.

Garey,

I don't know right now. It will be a few days before I can get it out of it's operating position.

Steve points out it could be a ground loop. It will take me time to try to check it out.

Right now I want to know what to look for.

The speaker is in the case with the AC-3 power supply for my T-4X.

OK. If it's early, 13 tube, I'd start by subbing V5 and V13. If late, 11 tube, check (bridge) C173 and/or C172.

Next step would be the old hardware check, i.e., check all ground and mounting screws for tightness, including PC cards,
terminal strips and socket mounting hardware.

Chris,
It depends upon whether you want to keep the "appearance" for histerical purposes, or whether you want it to just work. Either way, you can contact Tom at Hayseed Hamfest (google it) and he can provide a replacement multi-section can of the identical diameter and height, or he can provide radial-lead electrolytics individually, so you can just disconnect the can, leave it in place for "appearances" sake and put the individual caps under-chassis, or if it is an axial 3 section cap, or the old yellow/orange kind you can also do the "above" by using the three radial lead caps, opening up the orange/yellow paper cap, gutting it out (not a pleasant task) placing the three seperate caps inside it, and blocking it up again with the new leads hanging out, so it "looks orginial". Whichever way you want to go, Tom can fix you up. Of course if it's a new can multi-section cap it would be more expensive. Next most expensive would be to send him the paper yellow/orange (sometimes blue) multi-section cap and he can re-stuff it. Cheapest is to order the 3 individual caps, disconnect the multi-section one, and install the 3 individual in it's place. The end result is all the same...a nice clean B+ from the power supply!!

Let us know how it goes.

Thanks for this Bernie. I've done a few radios in the past, and typically just work under the chassis. I'm not clear about the capacitance values for this can. Each section has a range - 40-80, 20-40, and 10-20. I have not dealt with this before. I guess I'll have to dig out a schematic, and see what the circuit says. Just thought that someone had dealt with this already. I'll contact Hayseed, but they don't list the SW-4A as part of their standard line of products.

Chris,
Call or email Tom at Hayseed Hamfest. He has seen all of these and can tell you in a minute what you need and likely has it in stock. He usually sends a voltage a bit higher than the original to allow for our higher modern voltages which helps too. Tom is a super guy to work with, and has values he builds for other rigs that he can offer for "odd" rigs as well.

I'm in need of the Drake's R4 Preselector vernier "inner shaft". The inner shaft in my R4B Preselector has worn to the point where it can't be fixed by adding a spacer. The inner shaft no longer looks the same as the original inner shaft.

If you have one that's in good condition, not worn down to a "nub" as mine is, let me know via email.

Thank you and 73

Hi Group,

I found some excellent 9MHz filters on Ebay which are ideal for the TR-4C transeivers only $50 for the upper, lower and AM. They are of German design, excellent, used them when I still lived in Switzerland.

Item number: 141008771238

There was some discussion of replacing TR-4 filters
a while back.

Does anyone have any stock TR-4C filters they would
like to part with?

It appears the LSB filter in my TR-4C is bad. It shows
quite a bit more insertion loss below 1500 cycles than
the USB filter.

I'd be interested in buying both upper and lower.

Thanks

Was there an AM filter for the TR line - I just looked all over my TR-4C and can't find anything but the two SSB filters. What's the story?

For the R-4 receivers there is an AM filter (instead of the jumper resister - but that is another story. True?

The TR-4 Uses the SSB filters for AM, that's why the fidelity is bad on receive.

18159. R4C AGC

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-01-17 19:31:40 UTC
From: GALE STEWARD
Topic: 17370 Message: 18159

Hi Garey,

I'm in the process of rewiring the AGC switch on an older R4C (S/N 16961). I'm using the schematic from your CD for S/N 16151. This receiver had a Sherwood AGC/relay switch installed which I'm removing to install in another R4C and replacing it with a stock switch.

In looking at this schematic (near the AGC transistor Q7) it shows a cap off of the collector designated C75 (.0024). However directly above it on the schematic is a .001 cap also designated C75! This cap is (correctly) labeled C75 on your pic of the First IF, 2nd mixer, AGC board.

I'm wondering that the correct designation for the .0024 cap is. I haven't removed the circuit board so I don't have the best visuals to all of the components.

I did find the correct wire connection to the common of the AGC switch but I was wondering if the "two C75 caps" has come up before. BTW, the R4C parts list doesn't list a .0024 cap anywhere, unless I missed it.

73, Stew K3ND

Kris -

There is a Red or Wht/Red wire coming out of the PTO on the bottom, accessible under the chassis.

000 on the dial should read 5.500 MHz, and 500 should read 4.900 MHz. Simpler to just set on frequency with the Calibrator

Easiest place to get the 9.000 MHz is on the wiper (center) terminal of the BALANCE pot. This may need to be tweaked
one way or the other to accommodate less than perfect filter response. Think of the letter "M" with the two peaks flat
on top, representing the filter bandwidths from 400 - 2500 Hz. The carrier sits in the "V" in the middle, approximately,
resulting in b/w of 400 - 2500 on either sideband. If the CAR OSC is off center by 200 Hz, one b/w will then be 200 -
2300 Hz, and the other will be 600 - 2700 Hz. Nominal adjustment is to adjust he CAR OSC slightly in either direction
until the noise sounds about the same on either LSB or USB.

Hi all,
AM is not a nice addition to any of the Drake transmitters. You can only run very low power, and using a less than effective modulation scheme. The sweep tubes will suffer at more than 20-30 watts input on AM. If you want to do AM, get something that was made for it. It was probably more of an afterthought on the Drakes.

Hi Al -

Agree, generally. AM was included originally as a 'compatibility' mode, since there was still considerable AM on the
bands when they were first introduced. Granted, it's not 100% plate modulated AM, but it IS 'sorta' compatible, and
actually makes a decent sounding signal with reasonable peak power, especially if the receiving station has SLOW AVC
available to him. It's at least as good as the DX-40 etc class, or any of the accessory screen modulators. It's also
compatible with a linear amplifier if you want a BIG signal.

But it is not, and will never be, as good as my ol Globe King 500, or even my Johnson Viking II for AM! :-) BUT, I
can still pick up the Drakes!

This discussion caused me to do some research. I found two articles on the web which may be of interest. One is at:
http://www.w8ji.com/amplitude_modulation.htm
The other at:
www.pa2old.nl/files/am_fundamentals.pdf

The idea of controlled carrier modulation is to maximize the power output capability of a linear amplifier while minimizing its power dissipation. In a transmitter like the Drake T4 all the power going to the antenna must come from the output amplifier. In addition it is not designed for a continuous high dissipation. In either an SSB voice signal or a CW signal the long term average is quite low because the duty cycle is low. This is not true of conventional AM where the carrier must be supplied continuously. Where a linear amplifier is used for voice modulated AM the overall efficiency is rather low so the power handling capacity must be considerably higher than would appear from just the carrier power. For many years in the early days of broadcasting linear amplfiers were the standard. The plate circuit efficiency of a Class-B linear amplifier varies with the strength of the signal it is amplifying in comparison to its maximum capability. The maximum efficiency approaches 70% but where a 100% modulated AM signal is amplified the efficiency for the carrier is only about 33% and the long period (sometimes called all-day) efficiency is not

much higher due to the amplitude distribution of speech. The cure for this in broadcasting was the adoption of plate modulated transmitters using push-pull Class-B modulators. The RF amplifier could then operate at nearly the efficiency of a Class-C telegraph stage, i.e. approaching 80% while the modulator dissipation varied with the audio signal being very low in the absence of a signal. The other approach in broadcast transmitters was the use of various kinds of "high-efficiency" linear amplifier circuits such as the Doherty amplifier and its variations. These were able to operate in nearly Class-C for the carrier so the overall efficiency was raised to nearly 70%. These amplifiers are complex and generally fussy to tune.

The idea of the controlled carrier system was to generate a signal which was compatible with a conventional constant carrier AM signal but which could be amplified by a linear amplifier with good efficiency. The system works by generating a signal of essentially constant modulation index, i.e. percentage of modulation. With no modulation the carrier level is adjusted so some very low value which will not exceed the ability of the amplifier to handle it without excessive long term dissipation. The total power of the modulated signal can not exceed the power available to amplify a single sideband signal without distortion. Nor can the maximum power at 100% modulation be greater than the amplifier could supply if amplifying a conventional AM signal. The difference is that with normal voice signals the overall dissipation is considerably less than would be the case if a constant amplitude carrier had to be handled.

The problem with a controlled carrier AM signal lies in the receiver. If a conventional AVC is used, that is, one with a rather short time constant, it will attempt to follow the carrier level. This results in the receiver noise coming up between words and an unpleasant pumping effect as the amplification varies at a sylabic rate. The cure, of course, is the same as for carrier suppressed signals, namely to use either a fixed gain or an AVC with slow enough release characteristic so that it does not follow the sylabic variation in the speech. When this is done its difficult to tell a controlled carrier signal from a conventional AM signal.

One problem with the Drake system is that it does not provide any sort of automatic gain control for AM. In this way it is really no different from many conventional AM ham transmitters, most of which did not include any sort of compressor or clipper. So, one must be careful of modulation level and monitor the output with something like an oscilloscope that will indicate the modulation level or provide an external gain control device. Because the AM system in the T4 bypasses the narrow SSB filters it has a fairly wide audio frequency range although its limited by the time constants of the coupling networks in the audio.

Note that most of the power in an AM signal goes to waste, this is the very reason that carrier suppressed single sideband supplanted AM for communications purposes, so the effectiveness of a fixed power output transmitter will be considerably less for any sort of AM than for SSB with similar peak power.

My carpal tunnel syndrome is getting to me..

Interesting! No one has ever picked that up, including me..... :-('Doubled' identifiers aren't all that rare in
Drake schematics, especially after a version change or two. You'll see things like 'C75A' and C75B' in those cases. But
I don't know how I missed that. I don't have an R-4C open on the bench right now, but I'll open one up tomorrow and see
what I can see. There were several changes in that immediate area over the four versions, but ALL included the 2400 pF cap.

The photos and parts list are ONLY specific to the last version, but I sure don't see an extra cap in the photo.

Hi All,

I've just got my TR-4C PTO on the bench. I've got:-

Black/White = Ground
Green/White = Signal Out
Red/White = Vcc (+11 volts)

Rig does show signs of having been tampered with though. Green/White wire total cold solder joint to vertical PCB underneath. Wire would spin freely in joint. So I'm guessing the radio was perhaps a little intermittent.

Some sort of grease used on PTO front end. Took ages to clean (most) of it off!

Slowly bringing her back to life.

73, Steve.

18170. MN-2000 Meter

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-01-18 06:02:49 UTC
From: <kmx888@...>
Topic: 6301 Message: 18170

I have an MN-2000 antenna tuner with a bad meter. The face etc. are fine but the mechanism is broken. I have looked on EBay and Ham Fests for quite a while with no joy. I am now in possession of an LJ5 power/swr meter. The original is marked HA.
The LJ5 has a face that is about 1/2 inch wider, 1/4 inch taller and 3/8 inch deeper.
The round body of the replacement meter is about 1/2 inch larger in diameter than is the old one as well as larger than the hole in the panel. The scales are the same. 0-2000 Watts on top SWR on the bottom.

Electrically is it likely that they are the same? If so does anyone have any good ideas for making the hole in the panel larger without creating a hacked mess?
Best,
Kevin

You might use a Dremmel tool with a grinder bit to ream it out to the correct diameter. A little patience and caution could produce a smooth round hole much like a factory hole.

Use a nibbling tool to enlarge the hole. It takes some time, but will do an excellent job. You will have to remove the panel to do this properly. To avoid marring the panel, orient the punch on the nibbling tool so it cuts from the front of the panel towards the back side. The meter itself will probably hide any scratches, but just in case.

Make the cut radially, from the center of the hole toward the edge. You can go the other way, around the edge of the hole if you want, but it is usually easier to control the depth of the cut (how much the circle is enlarged) by using lots of small radial cuts. In any case, you will probably want to mark the panel so you don't cut too far toward the outer edge. Roughly the same number of "nibbles" will probably be needed whichever way you choose to go.

The tool will take an approximately 1/4" by 1/16" "nibble" each time it operates. Smooth the hole, if that matters to you, with gentle strokes from a half-round file.

When enlarging holes, be careful not to take too much "bite", as the spacing between the outer edge of the meter body and the required hole is most likely fairly close. You don't want the hole to extend past the meter body.

You may have to drill new holes for the mounting screws. One way to mark them is to dab a bit of nail polish on the screws and press them against the panel. Sometimes "magic-marker" ink works just as well. You may also be able to generate a drilling template from the panel where the replacement meter came from, if you are "rescuing" the replacement meter from a non-working item.

Kevin
Are you absolutely positively sure the meter is beyond repair?
All it cost to find out is postage to Eldad Benary at the sound company in Long Island
He is aces at meter repair and very reasonable

If you must enlarge the hole, one method I have used to enlarge a round hole on the same center is put two hole saws on same arbor. One that fits the existing hole and a larger one for the new hole. Use a vs drill and go at it carefully slow speed. Works very well on re-boring door for dead bolt locks to a larger new mechanism.

A Dremel tool with the sanding drum works well to "chase" a hole to a slightly larger diameter or smooth out a rough cut. Just position the tool so it is cutting into the work rather than spinning around wildly and let the tool oscillate round the hole. I call it chasing. The dynamics of the proceedure makes a very good approximation to a perfect circle.

Very dumb question here:

Why couldn't one take the meter movement assembly out of a W-4 and use it with the MN-2000 meter face?

I am not sure it is beyond repair, it is beyond my skill set for certain. I will try to find Mr. Benary and see if he can be helpful.
As you know the face and gauge face just pop right off leaving the mechanism bare. If I had another mechanism I could pop it right in.

I have gotten some good suggestions for methods to enlarge the hole but it is my last resort

Does anyone know if a W4 meter would work as a replacement? Could I just put the MN-2000 face on it?

Also does anyone know it the movement I have is the same technically as the one I am replacing. That was a very good point,, as was "testing" it before I started cutting sheet metal.

Best, Kevin KS0ILM

If you have a bench or floor drilll and a decent set of hole saws available.

Piece of decent say 3/4" plywood larger than the MN2000 panel.
Hole saw pilot hole drilled through the ply.
Clamp the ply to your drill shelf, and clamp (well clamped) the panel to the ply with the drill hole exactly centered in your meter hole. Panel clamps to as close as you can to the enlarged hole area to be.
Clean the back edge where the drill came through and do go slowly. Carl WD8NHK

18185. File - Bi-Weekly Statement

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-01-19 19:16:31 UTC
From: DrakeRadio@yahoogroups.com
Topic: 206 Message: 18185

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

73, Garey - K4OAH

June 2011 information posted on other Drake Repair / Restoration Reflectors.

Drake used the Jewell MS2T meter in the Drake W-4 Watt/SWR Meter, as well as other pieces of equipment (some antenna tuners, such as the MN-2000).

The specific meter used (Jewell MS2T) a Small core type movement, Taut band, 200 uA at 225 ohms
with a Red Knife Edge pointer and RF 0-2000/200 RF WATTS meter scale.
Part number (Larson Metercraft): JE119003-100-R

Jewell Instruments, LLC
850 Perimeter Road
Manchester, NH 03103 USA
1-800-METERS-1 (800-638-3771)
http://www.jewellinstruments.com/meters-and-avionics/panel-meters/analog-meters-product-list/ http://www.jewellinstruments.com/meters-and-avionics/panel-meters/analog-meters-product-list/

The Jewell Instruments catalog (2011) showed the MS series (Rugged category)
While Jewell can ramp up production for a large order, when I talked to them in 2009 --
the MS2 series appears to be ending production.
http://www.jewellinstruments.com/meters-and-avionics/panel-meters/analog-meters-product-list/#Jewell http://www.jewellinstruments.com/meters-and-avionics/panel-meters/analog-meters-product-list/#Jewell

MS-series product sheet (2013 Jewell product sheet shows - Still Available)
http://www.jewellinstruments.com/wp-content/uploads/2012/11/Jewell-MS-Series.pdf
http://www.jewellinstruments.com/wp-content/uploads/2012/11/Jewell-MS-Series.pdf

According to Bob Larson, at Larson Metercraft ---
Jewell (now part of Hoyt Meter in NH) made 4 different versions of their MS2 Series ..

MS2 (OLD LARGE MAGNET pivot and Jewell movement)
MS2TB (OLD LARGE MAGNET Taut band type)
MS2T Small core type movement Taut band -- THIS IS VERSION - DRAKE USED
MS2CM Small core type pivot and Jewell
===
I restored a broken Drake W-4, SN #10 wattmeter .. that also had a damaged meter movement.
Bob Larson at Larson Metercraft replaced my damaged movement.

RAM Meter in Michigan is a GOOD CONTACT fir Repair or Meter Mivement Replacement.
Bob Larson at Larson Metercraft (California) is another Jewell repair center for older Drake meters.

Stew -

Near as I can determine, there is no 2400 pF cap! I've looked at two fairly late R-4Cs, and neither has one. Bill
Frost doesn't recall anything about it. I think it may have been in the original design, but was removed very early on.
It's shown on all schematic versions of the R-4C, but I don't have an unit to check. I would guess it was replaced with
the 0.001 uF C75, and accidently left behind. There is no similar cap in the R-4B, which has the same AVC circuit.

In making the CD, I made the parts list from the schematic, and when I located each part I would add its description to
the list. Apparently I found the 0.001 uF 'C75' and missed the 0.0024 uF one! My only excuse is that it was my first
attempt at this project and just missed it. Two other experienced techs proofread the original documents, but ......
:-) I think I'll just record it now, and if I am able to access earlier s/n units evaluate whether to remove the cap
from the schematic, or add a C75a to the Parts list.

Thanks for pointing it out, and I'll let you know if I come up with a 'good' answer! :-)

Good afternoon,
Back in the summer I purchased a R8B used from universal radio. So far, I love the radio. Functions excellent and has quality sound. Since there is no active R8 groups out there I hope there are a few here that will share their thoughts. I have mine set up for computer control through SWLog program.

Mine is a R8B with vhf unit. On shortwave and am broadcast I am finding out the performance is exceptional.
I like computer control but one draw back I am having is my big flat screen monitor is causing some interference. So my limited space on my desk will have to create something that will not cause the interference but still have toe radio within hands reach.

Date: 2014-01-21 20:34:53 UTC
From: John Wingard
Topic: 18192 Message: 18201

I've tried several times to join the R8 Yahoo group and I did leave comments that I was a long-time R8 owner as well as owning other Drake gear since 1976. I even gave my call sign if they wanted to see if I was an amateur (not that it should matter). For the record, I've never been allowed to join, and in fact, I have received no response at all from the moderator or anyone else. I'm not sure what type of member they are looking for, but I don't really care at this point. This group is much better!

73, John - WB4GLJ

Glenn -

Yes, it's a pretty inactive group. Still have 600+ subscribers, but last post was Dec 3, 2013. Did you notice this
'Notice' from the info page???

"***NOTE*** If you are requesting membership, you MUST leave a comment in your request as to WHY you want to join. An
empty (no comment) request will be denied."

Anyway, you're welcome here, and there are at least a few 8's around! :-)

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-01-21 20:42:59 UTC
From: Barry
Topic: 18192 Message: 18203

Owners and moderators may simply no longer manage the list (illness, inattention, other). I belong to a group where I was a moderator and the owner simply stopped participating. It took me years to find the owner and get the group transferred to me. Unfortunately, Yahoo will not help in this case as it is a violation of their ToS contract.

Regards,
Barry - N4BUQ

18204. Re: [DrakeRadio] R4C AGC

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-01-21 20:47:28 UTC
From: GALE STEWARD
Topic: 17370 Message: 18204

Thanks for all the research Garey. I have two R4Cs open and can't find a 2400 pf cap in either one. There is no 2400 pf cap listed in the parts list either. Interesting...

I was able to ring out the wiring from the AGC board to the AGC switch without any other issues. That's what started the search for the missing cap as I was spending a lot of time working with the schematic in the area of the AGC board (checking, re-checking, etc.).

73, Stew K3ND

To: DrakeRadio@yahoogroups.com
Sent: Tuesday, January 21, 2014 12:28 PM
Subject: Re: [DrakeRadio] R4C AGC

Stew -

Near as I can determine, there is no 2400 pF cap! I've looked at two fairly late R-4Cs, and neither has one. Bill
Frost doesn't recall anything about it. I think it may have been in the original design, but was removed very early on.
It's shown on all schematic versions of the R-4C, but I don't have an unit to check. I would guess it was replaced with
the 0.001 uF C75, and accidently left behind. There is no similar cap in the R-4B, which has the same AVC circuit.

In making the CD, I made the parts list from the schematic, and when I located each part I would add its description to
the list. Apparently I found the 0.001 uF 'C75' and missed the 0.0024 uF one! My only excuse is that it was my first
attempt at this project and just missed it. Two other experienced techs proofread the original documents, but ......
:-) I think I'll just record it now, and if I am able to access earlier s/n units evaluate whether to remove the cap
from the schematic, or add a C75a to the Parts list.

Thanks for pointing it out, and I'll let you know if I come up with a 'good' answer! :-)

From: <kmx888@...>
Topic: 6301 Message: 18209

Great information, now for some questions, please bear with me. If I look around for an MS2T meter I can find them but they seem to be for many uses (Voltage, amperage etc). I have always assumed that most meters are actuated by the movement of current through them. What they are portraying to the user is indicative of the circuitry used to feed the meter. In other words a voltage meter may indicate voltage but is reacting to the amount of current passing through it.

Here is an example of a MS2T meter being used for voltage measurement
.http://www.bmius.com/p-12932-dc-volts.aspx

Can I assume that within the universe of MS2T meters there are several different "innards"? I see from the Jewell catalog that there are many different ranges and resistances.
http://www.jewellinstruments.com/wp-content/uploads/2012/11/Jewell-MS-Series.pdf

If I am correct..... I guess I am on my own with out exact part numbers etc?

Kevin -

Deal with RAM Meter, which handles these specific questions about Jewell MS series meters and the 4 different movements.
The main support person (I have lost his name) for Analog Meters is a radio amateur.
===
Currently headquartered in Troy, MI with sales offices in Pennsylvania and Connecticut, Ram Meter Inc. has been doing business for over 75 years. It all started in 1936 on a dining room table in northwest Detroit when Russel A. Monnier (R.A.M.) began repairing electrical indicating instruments for United Motors Service, his employer at that time. It wasn't long before he quit his job to dedicate himself to repairing these instruments full time. Russ named the business Ram Meter Service and it has continued to grow ever since.
In 1962, Ram Meter Inc. became one of the first panel meter "Mod Centers", a concept where we bought blank meters in volume from the factory and modified them to the exact specifications of the customer. To this day, we continue to offer that service and can modify analog and digital panel meters with non-standard scaling, company logo's, special calibrations, color bands and just about anything else to help fit your application.

I'm trying to find parts for a Drake PRN-1000 shortwave receiver. This was made back in 1995 according to the date on the circuit board. I need the assemblies for the TONE and VOL ON/OFF. These are both small printed circuit boards with a small potentiometer attached to them. I don't see a part # on either one of them, just the words TONE on the tone control board and VOL ON/OFF on the volume control. Does anyone have a source for where I could purchase these, or at least a part number? This receiver is almost identical to the Drake SW1 shortwave receiver. Thanks!

18214. Sidetone Issue

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-01-22 16:35:19 UTC
From: Michael A. Kelly
Topic: 18214 Message: 18214

Hello everyone,

I have an issue that occurs in both my B and C Line Twins. When I am transmitting CW, using headphones, there is a steady, lower single note sidetone that is continuously heard in the background. The C line's background tone is louder than the B Line. It is independent of the actual CW characters being sent and at a much lower in volume. As such, it might not even be much of an issue if one was not using headphones, but it is very noticeable when you are. Unfortunately I run 100% of the time using headphones.

On the T-4XB, if I turn down the GAIN and drop the power (and the overall level of the sidetone) it becomes much less … and of course, if you turn it down enough then the vox will drop out and it will not remain in transmit… when it is running with enough drive to read about .3 on the plate amp meter, it is low enough that it is tolerable, but I know this is not normal. If I load up to 350 mils, then it is quite a bit louder in the background.

Any idea what this steady sidetone is in the background and how best to remedy it?

Thanks,

Michael NZ4D

Michael -

Almost certainly this is the electrolytic cap (C129 T-4XB) or (C107 T-4XC). You can check by connecting a good cap in
parallel with each of these.
Replacement cap(s) available from Hayseedhamfest.com.

Secondary possibility is the switching diode (D8 T-4XB) or (CR15 T-4XC). Check voltage across diode. Should be -0.7
VDC or so key UP, and +15 VDC or more key down.

If no luck, check back here!

Jim -

Same capacitor! 60 uF @ 250 VDC Twist-Lok. Risky to just add one across, as original may still fail shorted. Best
to replace, or at least clip leads to disconnect original from circuit.

X = C132
XB = C129
XC = C107

18218. Drake C-Line and N3ZI Super DDS

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-01-22 19:15:22 UTC
From: <dcoffman@...>
Topic: 18218 Message: 18218

I'm looking at implementing the N3ZI Supper DDS to control the transmit and receive frequency of my C-Line Twins. My thought was to build the DDS in a separate enclosure and attach it to the injection line of the R-4C to control the TX/RX; leaving the injection line disconnected from the T-4XC.

It is my understanding that the DDS does not have enough output to properly drive the injection line so a buffered amp may be required. Has anyone experimented with this and what are the thoughts of this implementation? I do not want to disturb the transmitter or the receiver but would be nice to have an external frequency display with the ability to accurately change frequency.

Thanks,

Doug - N9XTF

I've been working (slowly) on using one of the AD9850 eBay modules to use as an FS-4 replacement. I've got the software kinda done and breadboarded up the circuit. I still need to add a buffer amp I think...I'll probably clone the W8DIZ all-purpose RF amp for that.

I used an SI570, which had a little more output than the AD9850 does (I think...haven't measured it), and it seemed to work OK, but I wanted to fancy it up a little and use an Arduino to control the DDS. I've got the software mostly done - for phase 1, anyway. Phase 2 is to add a frequency counter for digital display.

I thought about just using the DDS as a VFO through the AUX XTAL inputs, but decided against that...mostly because I wanted to tune with the PTO. I was able to read the frequency from the INJ jack in my R-4, so it looks like adding a digital display won't be very difficult.

Hopefully I'll get off my lazy hind-quarters and finish this up before too long...I've started putting the parts on a perfboard, but now I've got to wire them all together - so far I've got my 5v supply done...I'll be sure and post here when I do finish up, and will look forward to hearing how your project turns out.

Doug -

I haven't tried it, but the first step would be to determine the input impedance of the INJ jacks on the R-4C and T-4XC.
Then a simple transformer will probably suffice. You need about 1.5 - 2 VRMS at the PreMixer frequency (7.3 - 35.6 MHz)
into either INJ input.

You might take a look at the PHSNA project Yahoo group for ideas. We used either a 2N5109 buffer or an MCI ERA-3+ MMIC
to get about +10 dBm into 50 ohms (0.7 VRMS) from a 9850/51. You need about +20 dBm _into 50 ohms_. I suspect the
input impedance is considerably higher, allowing use of a simple transformer to get the higher voltage.

Really not nearly as simple a project as it looks, to do it right. Do you REALLY need to know your frequency to better
than +/- 100 kHz?

Garey,

I really expected some severe blow back from hard core boat anchor guys on this one. No, the frequency accuracy is not of great concern however; it would be easier to get on the correct frequency when operating SSB, when in a group, instead of attempting to tune to one person's voice. It would also be nice to see if the VFO were drifting and compensate for it.

As always, I greatly appreciate the information. I knew it wasn't going to be a simple plug and play thing but was not sure how much trouble I was going to get into.

Hello Doug,

much has been said already. An MMIC is definitely a good choice due to it's simplicity. All it needs is two decoupling capacitors, a resistor and a choke. 50 ohms both on input and output already, so no hassle with matching. I used an ERA6 in my DDS for the TR7 but the level is a lot lower there, just about 4 dBm.

So you may use the ERA6 (or another ERA) as a driver after your AD9850 and then transform your voltage up using e. g. an Amidon FT50-43 core as a 1:4 oder 1:9 transformer. A lot can be found on the internet about how to wire it up. Just google "FT50-43 1:4". Make sure you terminate the transformer with the correct impedance like 200 ohms or 450 ohms and measure the voltage with a scope or an HF voltmeter.

Good luck

Garey,

Based on your suggestion this summer, I acquired and built the Ensemble RX II I believe it was. Quite a fun little receiver and I must admit it receives really weak signals quite well!!!

I've always tuned my transceivers or receivers to what sounds normal to the ear. People do make a point to point out when I'm off frequency. I do not have an issue on my solid state stuff but the tube gear is a different story.

Thanks for all the input,

Doug - N9XTF

The comment in the Super DDS thread on being on frequency brings me to a day-dream , making an RIT board as per the TR-4CW/RIT and adding it to a TR-4C. Has anyone made one of the RIT boards as per the diagram in the manual?

Not using the NB knob would free up an existing hole in the front panel, and a push on off in a 10k pot should be an easy retro fit (and easy restrore to original) for the RIT control.

But has anyone done it?

Check the value of the cathode resistors of the finals.
If they are off value (quite common) replace them. Garey
recommends metal oxide thick film type. If they are on value
measure the drop across each one. This will tell you the
cathode current of each tube. If you have correct voltages
on all tube electrodes and low current it is usually due to
weak tubes but measure the current at the cathode resistors
before deciding the tubes are NG. Be careful because there
is high voltage in the compartment from the screen supply.
If you get the correct voltage at the cathodes
(indicating correct current) you must go over the metering
circuit again. There are many carbon composition resistors
in the T4XB. Depending on the brand they may be quite close
to value or have drifted very high. On my T4XB I found two
different kinds of resistor, one with a smooth case, the
other with a seam. The smooth one was within specs, the
seamed one, I think something like 50% high. They are not
to be trusted.

The problem I have with SSB contests is they don't talk long enough to let you tune them in!

I'm not a contester but I use the contests to check receivers.

I can see what kind of path we have here to Seattle.

OH, yeppir. . . . . you’re right on the money there. Situation normal for sure.
You certainly can hear this on HF too, as I’m sure you have. Along with
Garey’s comments about “channelization.”

☐
I monitored the VHF contest last weekend. In most cases no one was on the same exact frequency. I had to tweak the LMO on the SB-301 for most if I wanted to understand them.

Even if everyone had a digital VFO the transverter LOs are not all on frequency. And most of these people do not have the test equipment of knowledge to fix the problem.

UH. . . . getting on the correct frequency when operating SSB instead of
just tuning to one person's voice. . . . . that's what I've been doing

for
50-plus years. Having someone else off a slight nudge never seemed
to bother me - unless they got set up far enough off that you KNEW
they must be tone deaf.

I tune for what seems to be a "natural" sounding voice whether digital
dial or analog. May be wrong today but I'm just sayin'. . . . . If you
happen to dial across a QSO in progress, what then? I just tune until
it sounds "right" to me.

The only time I concern myself with the correct frequency is with
digital signals and I need to know the center frequency.

Doug -

As pointed out by another list member (privately!) I should have said "+/-
0.1 kHz"..... My Heathkit AR-3 can get
better than +/- 100 kHz..... :-)

I'm probably the biggest Luddite on here when it comes to modifying Drake
gear. As long as it's not destroying the
gear, I don't have a problem with someone doing it to 'their' radio, but I
WILL ask _WHY?_!!

I'm about 98% CW, so find it hard to understand the _MUST BE ON CHANNEL_
meme of the SSB crowd. It's hard to find a
QSO now that is NOT on some even 5 or 10 kHz frequency. I musta missed when
the FCC made us 'channelized'. :-)

I've heard arguments go on for longer than I cared to listen between members
of a group about what frequency they were
on. In many cases, NONE of them were actually on THE supposed
frequency.......

Not that simple. The RIT PTO only has a varicap and associated circuitry in it to allow RIT, similar to the 7 Line
PTO. The small PC board with an analog switch IC (MC14016) merely sets the bias for the varicap and does the switching
back and forth.

It might be possible to 'pull' the band oscillator a little with a varicap, but I'd be reluctant to muck around in the
PTO. It might also be possible to shift the CAR OSC but it would have to be switched back out for transmit.

Not a trivial task, in any event.

You're not clear if you are measuring NO, too little, or too much PLATE current.

Check voltages on all PA tube pins. IF the Plate and Screen voltages are present and the Cathode is grounded, the tubes
will pull maximum current, to destruction! A negative voltage on the Grids (~ -62 VDC) limits that current to 0.07A.
This is regardless of any other voltage or stage in the radio. The Cathode pins in SSB should read about 150 VDC key or
PTT up, and about 0.5 VDC key down or TUNE position. The 15 ohm Cathode resistors of the PA should drop about 0.53 VDC
each, IF they are 15 ohms. Measure! You can measure the voltage drop across R36 to measure actual current. Verify
that R36 is 2.7 Ohms.

If voltages are good and still no current, the PA tube(s) are bad. I HAVE seen tubes that heat and look good that will
pass NO current. Most likely you have a resistor or two that has gone up in value with age, probably R32 and/or R33.

Be careful measuring in the PA compartment UNDER the chassis, as both Plate and Screen voltages are present. HIGH VOLTAGE!!

Think about it a different way: Run the twins in transceiver mode and connect a digital dial to the injection jack via a "Y" connector - I run transceiver mode with the R4C controlling the frequency of both units and have a Digital Dial on the R4C injection line here. I can easily check the calibration the Digital Dial against my Icom R70 and it's as accurate as the Icom that reads three digits to the right of the decimal. Check out the ESP DD-103. That's pretty plug and play.

Garey,
I really expected some severe blow back from hard
core boat anchor guys on this one. No, the frequency
accuracy is not of great concern however; it would be easier
to get on the correct frequency when operating SSB, when in
a group, instead of attempting to tune to one person's
voice. It would also be nice to see if the VFO were
drifting and compensate for it.
As always, I greatly appreciate the
information. I knew it wasn't going to be a simple
plug and play thing but was not sure how much trouble I was
going to get into.

When you run the twins in transceiver mode you do not have independent tuning of the receiver. So if you adjust the VFO to clarify the speech you also change your transmitting frequency.

I also have a Kenwood TS-520. It has a RIT knob that works very well.

When I use one of the sets of twins I ZERO BEAT the transmitter against the receiver then never touch the transmitter VFO again. I can fine tune the receiver all I want and the other person is not aware of it.

If you really need a DIGITAL VFO use a RICEBOX!

The digital dial will give you the frequency accuracy if you really need it.

Hi Garey,

To the group, Gary is correct. I have one of these. Was when my local radio club was running mobile using TR7's (long time ago) and the white does in fact feed positive on a separate pin from the red. Low bat. drain configuration. Normally a slightly smaller gauge wire on the white. Carl WD8NHK

Putting a DDS in place of the PTO does not solve the problem of frequency accuracy. You would need to replace the heterodyne oscillator with a DDS also.

You are correct in that it is a frequency counter only.

Garey,

I really expected some severe blow back from hard

core boat anchor guys on this one. No, the frequency

accuracy is not of great concern however; it would be easier

to get on the correct frequency when operating SSB, when in

a group, instead of attempting to tune to one person's

voice. It would also be nice to see if the VFO were

drifting and compensate for it.

As always, I greatly appreciate the

information. I knew it wasn't going to be a simple

plug and play thing but was not sure how much trouble I was

going to get into.

You know Garey, that was what I was thinking. As a lark, I hooked up the cable to a 35 amp Astron I have... Hooking up just the red and black leads. I measure the voltage out of the plug and got 13.5 volts out pins 13/14 and there was no voltage on 15/16. I can always hook up the white lead and measure .. just not hooking up the TR7.

Joe -

I've never thought of running a TR-7 mobile, but perhaps the white wire is to power the 'rest' of the radio via Pin 15,
and the PA only via Pin 13. ??

Joe -

Correct. The power connector on the TR-7 has two DC inputs. Pin 15 is the radio, with the exception of the PA stages.
Pin 13 is the PA stages only. Both must be present for the radio to operate.

The reason is that the heavy current causes the voltage to drop when the radio is keyed, even with very large wire. By
powering the radio from a separate lead, they eliminated dimming of the panel lights and other regulation problems. Now
the voltage at the radio is only affected by the regulation capability of the power source rather than the drop across
the PA power lead.

Bob, You are welcome.

I don't know much, except that you want to use transparent tape for the final label, and use vertical mode. The trick is to figure out which size, spacing and so on, and I don't know them.

The machines are relatively cheap, and have many uses besides SPR-4 dials.

I have a handheld one, there are desktop ones (slightly larger and a different shape) and a USB printer. The USB printer seems attractive to me because I could experiment and it would be easily repeated, but I never got around to buying one, the handheld works so well.

18255. R4 RF immunity

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-01-23 18:01:07 UTC
From: <teamkarst@...>
Topic: 18255 Message: 18255

My R4A, 11 tube box has a bit of sensitivity to RF fields. Something I might expect more with solid state gear, but here is my situation. I use a headset, and I hear what you may call splatter in the earpiece during transmit. I can also hear a tone during tuneup of the transmitter. This audio is not affected by the Rx volume control. It does also present itself thru the speaker, with the headset disconnected.
And the last big item; it only happens with the SB220 on! Operating position is in the basement, with the flat top dipole about 45' above ground, but only maybe 30' offset from the station, so is maybe a total of 60-70 feet away. RG8X feed, no line chokes, using a MN2000 tuner. No doubt, there is some local coax radiation.
That all said, the interference goes away, if I move the Rx line cord to a different AC outlet (same branch circuit) from the Tx/AC4. Since I use a outlet strip to control the 4-line power on/off, I'm bound and determined to fix this, a couple of snap-on's on the R4 line cord didn't make a noticeable difference. My next step is to try an ISOBAR power strip, that has built-in RF filtering.
Is this affect seen by anyone else here?

From: Garey Barrell
Topic: 18255 Message: 18256

That's a new one! :-)

I wonder if the 'stuff' is coming out of the SB220 and merely being detected by the R-4A? I guess I would check that
the AVC line in the R-4A is correct. A leaky filter cap could be loading down the -80 VDC supply. The AVC line should
go to about -30 VDC in STANDBY, which thoroughly shuts off the RF and IF stages.

Since it's a Late one, it has solid state low level audio, which might be more susceptible to strong RF fields. I don't
see HF getting into those stages any way other than the speaker leads. Might try your ferrites on those, and/or
shorten, coil or re-route them.

Please let us know what you find!!

18257. Re: [DrakeRadio] R4 RF immunity

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-01-23 18:54:48 UTC
From: Evan Rolek
Topic: 18255 Message: 18257

This is not uncommon and can be due to a variety of causes. Ground loops, device rectification within a receiver, poor shielding, poor grounding, etc. etc. can all contribute to this as a possible cause. Off hand, the situation seems like RF pickup might be coming in via the AC line in the house and/or the line cord of the receiver. It is a bit strange that a different outlet on the same circuit produces a different result/cure. It is almost suggestive of a poor ground, neutral, or other connection in the outlets, etc. Sometimes just reversing the line plug to the receiver can produce an improvement.

As to RF filtering, there are varying degrees of filtering and often the more you pay, the better the filtering but that is a gross generalization. If it were me, I would do further investigation to determine if the problem is caused by radiation and/or conduction. Depending on the cause, it will lead you to the respective cure(s).

Please keep us informed so we all can learn.

73,

Evan, K9SQG

18258. RE: [DrakeRadio] RE: Drake C-Line and N3ZI Super DDS

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-01-23 19:02:38 UTC
From: Doug Coffman
Topic: 18218 Message: 18258

Bob,

I was waiting for one of these quick retorts, I'm just surprised that it took this long. If you will take the time to read the thread, I stated that I DO NOT need the frequency accuracy of a RICEBOX! This is a curiosity, experimentation, implementation of something new that MAY or MAY NOT be helpful in my operating station.

It's much more helpful on a forum to give reasons for or against a project, for instance; the DDS does not have enough output and of correct impedance to work. You would have to build a number of subsystems to make it function and either the cost or expertise required may be more than you have. Or maybe something like give it a try and you may have to build X,Y and Z to make it work properly.

So far as I know, Ham radio has always been about experimentation and learning. Your comment leads me to believe that your belief is that one should keep using the products that they have been given and not try to learn, experiment or improve the product. If that's the case then I'm sorry because I do not make a very good follower. This post was not about need, because let's face it that's a relative term. I do not need 7 Drake radios, I do not need 4 amplifiers or any amplifiers at all etc. etc. The only things that are needed in life are food, water and shelter; the rest of the items we have are luxuries.

As a follow-up, If you are going to post something, why do you not take the time to make it useful to the recipient. Albeit I could have misunderstood the tone of your message, and if so then this post should be disregarded. If in fact I did get the tone of your reply correctly then it reminds me much of the curmudgeon on some of the Eham forums, of which I can do without.

Regards,

Doug Coffman – N9XTF

Bob,

I printed some SPR-4 labels once using Avery 5660 clear laser labels on a standard laser printer. Created the labels in Microsoft Word. Took some editing to get them the way I wanted them, but they turned out pretty good. Will upload a picture of the crystal selector dial that I took while I was working on it to the Photo section.

Are you grounding the chassis of the receiver and
transmitter separately from the coax shield? If each piece
of equipment should be brought to a common ground point
through heavy wire or better braid. If you have a ground
disconnect it temporarily and see of the problem changes.
Note that its important that each item be grounded
separately to a common point otherwise you will get a ground
loop.

I am using a solid copper, 3' long grounding buss for the station (metalwerks). Each Drake "box" has its own #12 to this bus. The SB220 has its own separately run 240V branch wire and has its own grounding wire to the same buss. I'm now armed with a corcom ac line filter, some more ferrite and will post future results to this forum. Thanks to all helpers.

In order to obtain some additional observational data as to whether the problem is due to radiated versus conducted RF energy, you might want to do some testing with a dummy load to get some additional insights.

I have 7 MMK7 Mobile mounting kits for the TR7.
and in every one the power cord only has 2
conductors, a red and a brown. These are covered with a gray jacket.
There are 3 wires coming out of the noise filter
that is in the MMK7, a white,white with black
stripe, and red. If you have a 3 wire power cord
for the TR7 it was probably made by someone other than Drake.

I have to agree with Joe. I have had three MMKs (the mobile mounting kit for the TR-7) that included the cable. None of them had anything other than two conductors. Not sure if Drake had another 3 wire variant or not.

73,

Evan, K9SQG

Joe -

Correct. The power connector on the TR-7 has two DC inputs. Pin 15 is theradio, with the exception of the PA stages.
Pin 13 is the PA stages only. Both must be present for the radio tooperate.

The reason is that the heavy current causes the voltage to drop when theradio is keyed, even with very large wire. By
powering the radio from a separate lead, they eliminated dimming of thepanel lights and other regulation problems. Now
the voltage at the radio is only affected by the regulation capability ofthe power source rather than the drop across
the PA power lead.

Joe -

Correct. The power connector on the TR-7 has two DC inputs. Pin 15 is the radio, with the exception of the PA stages.
Pin 13 is the PA stages only. Both must be present for the radio to operate.

The reason is that the heavy current causes the voltage to drop when the radio is keyed, even with very large wire. By
powering the radio from a separate lead, they eliminated dimming of the panel lights and other regulation problems. Now
the voltage at the radio is only affected by the regulation capability of the power source rather than the drop across
the PA power lead.

I have 7 MMK7 Mobile mounting kits for the TR7. and in every one the power cord only has 2 conductors, a red and a brown. These are covered with a gray jacket.
There are 3 wires coming out of the noise filter that is in the MMK7, a white,white with black stripe, and red. If you have a 3 wire power cord for the TR7 it was probably made by someone other than Drake.

Marco -

Welcome to the DrakeRadio list.!

Before you make your final decision on the AC-4 upgrade, take a look at the board set offered at Harbach Electronics
<harbachelectronics.com>.

I have used both, and the two products are of equal quality and operation, just different mechanically. You might also
check your power transformer in the AC-4. Some have the transformer bolts in the other direction or covered in epoxy
and won't accept the stand-offs of the Heathkit shop version.

A plus or minus for the Harbach version is that the PC boards are already assembled, and how much you like stuffing and
soldering boards! Some of us find that to be the best part.

Ray -

Be SURE these voltages are at zero before touching anything in the transmitter. Again, there is +650 VDC UNDER the
chassis, along with the +250 VDC.

If these are voltages _at the tube pins_ the tubes are drawing Plate current. Sometimes the voltage gets 'lost'
between the socket tab and the pin, so best to touch your probe to the tube pin itself where it protrudes through the
socket.

However ...

If R36 measures 3.9 ohms, (10.9 / (17.9+3.9 = 21.8 ohms) = 500 mA through V5!! Not likely, unless it's melted down into
the socket. And;

then 5.7 / (3.9 + 18.1 = 22) = 260 mA, also enough to melt V6.

So.... We have a problem. The above assumes that the ''bottom" end of R36 is at 0.0 VDC, which it should be IF the
relay contact is closing properly. If not 0, what IS the voltage? Measure resistance from the bottom of R36 to chassis
(Power OFF) while depressing the armature of the relay with a pencil.

What is the color code on resistor R36? It should be Red/Violet/Gold. If it is, it has gone up in value and should be
changed. Not immediately, it's good enough for troubleshooting as it is. IF the color code is Orange/Blue/Gold, it's
probably been replaced with the wrong resistor. Again, not an immediate problem.

You can measure the current through each tube by measuring the voltage ACROSS R32 and dividing it by 17.9; and R33
divided by 18.1. Both these need to be replaced with 15 ohm, 1 W ceramic composition resistors, but again are 'close
enough' at this point.

The consensus seems to be that this is not a "standard" Drake cable. Seperate wires for the high and low current rails are a very good idea that seems to be a well kept secret. GW4ALG mentions it on his mods page, but few seem to talk about it otherwise. I have seen some pretty wimpy homebrew and aftermarket power cables for the TR-7. This radio needs a beefy power cable, and can benefit from a 4-wire cable. Having done this with both a generic cable and a PS-7 retrofit I wouldn't have it any other way.

Hello from COLD N. Alabama!! 16' now at midnight, going to 9' by morning
too cold for a Southern Boy.
I have a newly acquired C Line that works beautifully Most of the time.
Then it will stop transmitting. I've tried it with the R4C controlling the
Transmit and also the T4XC and it does the same thing. You can hear the
relay clicking but no output at all, turn it off for a while and try again
and it probably will work and continue to work. I had my Etek in line and
took it out thinking it could be in it or the Y adapter but it still does
the same thing. Took the relay out of the T4XC and lightly burnished the
contacts with no progress. Other than that it works great and solid as a
rock after about 15 min. warm up time.
Any idea's??
Thanks

Woody,

The official name for this weather is Global Warming. We've been getting below zero at night for a couple of weeks now with wind chills at -15 or so. Spring can't come soon enough. Nice WX for antenna work.

Does this happen on all bands?
Has each swich and potentiometer been moved through all the positions (with or without DeOxit) to remove possible oxidation?
Is the 12 pin Jones connector from the power supply snug against clean contacts on the T4XC?
Do you have a way to substitute/test the tubes? (not the finals, but the other tubes)
If it were me, I'd make a visual inspection of all solder connections on the bottom side.

My mind isn't clear right now. My mom, who is 101, is not doing well. Sleeping all the time and hasn't eaten in 2 weeks.

73,

Evan

Woody,

The rear power connector pins and plug, over time, can become corroded causing all kinds of problems.

I use DeoXit applied to the power pins then scrub the pins with an old tooth brush. The plug itself, can be cleaned. Pull the main power supply's AC main plug from the wall outlet. Apply some contact cleaner to each socket on the power plug and insert and remove the plug from the rear of the Transmitter a few times. Use canned air or compressed air to remove any cleaner residue from the power connector pins and power plug socket then plug the power plug onto the rear pins ensuring it is flush with the rear panel. Power up the xmtr and test for power output in a 50 ohm dummy load.

Have you tried "tapped" on the cabinet, when you loose RF output, to see if the RF comes back? I had the same problem, loss of RF output with my T4XC xmtr, and it turned out to be T14, the balance modulator transformer.

Hi to the group,

TR7 stuff
First symptoms and past tense...screwed up frequencies and readouts 2 megs off...low EG 14meg is 12 Meg. 7Meg is 5 meg
Could use the up down buttons to get to 14 M stuff that worked as well as what appear to be 7M. There were also signals in the 21 M region as I recall.

Last step, pull the DR7 board and substitute the extender set jumper board, all straightened out. Obvoious no digits, and no up/down.

Substituted a second DR7 board (no digital reads) and all is straightened out too. So its apparent that the problems are on the DR7.

Considering that the up down buttons have always worked it would appear to me that changing the two CMOS chips (14050's) U9007 & 9008 should fix the original headache. That's all that's on the jumper board.
Am after a thought conclusion or not on the above consideration statement.
73's , Carl WD8NHK

PS Can't leave well enough alone
In the meantime, the original DR7 board that had digital read but screwed up frequencies was being used to ferret out the problem with the second DR7 board with good frequencies but no digitals....SIGH...
Scrounged an O scope, looking at patterns for what its supposed to do.
I blew out U9019. Clumsy oaf.....new chips on the way, perhaps fix both DR7 boards., more work.

It's worth noting that the band programming logic on the DR-7 will function perfectly normally with PROM U9003 removed completely. What you loose is the UP/DOWN "stops" at the range edges printed on the bandswitch and the H.B. flag to the transmit innhibit circuit on the D.C. board.

Hi to the group,

Working on a couple of TR7's
One has been a work in progress for several years and I have already had one message out today on it. Thank you for the response Garey.....Yep! That's my "Crud"

The other one may require a group consensus.
Unit # 1513 an early one.
Has had the cover off once prior to me.

There is no gas fuse across the RFC choke on the back panel, antenna input.
No braided ground strap on the PTO. Drake did that standard later, and on any repair unit.
What else am I missing that could or should probably be done, to bring it semi up to par without replacing any boards.

He said "removed completely"... And in fact that is what
happens...nothing The main purpose of the PROM is the band edge
feature in conjunction with the up/down buttons.

So without (!) U9003 the TR7 works just fine unless you push the up/down
buttons.

Garey

The R36 is at ground with out relay in gaged also at ground when relay is in gaged . Tried 3 different meters . Shack is in separate building got heat on now Going back in hour to do rest you suggested .

Thanks 73
Ray

From: Jim Shorney
Topic: 18279 Message: 18289

Correct. The UP/DOWN buttons still work fine too. You just lose the stops. This allows you to step outside of the band range limit. The radio still works as long as the PLL stays in lock, but performance degrades the farther you go as you get into the skirts if the high- or low-pass filters. I had mine runnnnig up tp 32.something MHz on 10 Meters before the PLL dropped lock. The danger arises from attempting to transmit through the low pass filter. If you get into the skirt area, which is possible on some bands, you could let the smoke out of some parts. Not an issue unless you have an allband transmit mod, but the mods fool with the transmit inhibit circuits and make this possible.

In that case removing U9003 and seeing normal syntesizer operation resume would identify the source of the problem.

18293. FS: Astatic cord for D-104

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-01-25 05:37:37 UTC
From: Evan Rolek
Topic: 576 Message: 18293

Fellow Drake Enthusiasts,

I'm cleaning up an old, unused Astatic microphone for my T4Xc and possibly Johnson Valiant. The original, unused cord is a two conductor cable, with one conductor being shielded for the mic input. The cable is black, with smooth rubber outer jacket, not a coiled cord. It is still wrapped as original from the factory and I unsoldered it from the G-Stand. It isn't suitable for my particular application so I thought I would offer it to somebody in the group that might be able to use it. I'll send it to the first responder for $5, shipped via Priority Mail flat rate box.

Enjoy those Drakes.

73,

Evan, K9SQG

18294. Re: [DrakeRadio] RIT for a TR-4C

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-01-25 16:09:41 UTC
From: <garywinblad@...>
Topic: 18218 Message: 18294

Doesn't the TR-4 have an "FSK" terminal on the PTO like other 4 lines?

An external varicap and simple control circuitry should allow RIT.

I have a Drake app note on how to do FSK on a T-4X,and have it implemented
in my T-4X by the previous owner... RIT should be real similar... and easy!

Gary -

Not exactly.....

Yes, the TR-4 PTO has the same FSK terminal as the T-4X. Works great for 170 Hz, or even 850 Hz shift. Thing is, it
only shifts the frequency UP, and unlikely you could get much over 1 kHz.

The SAME terminal on the PTO for the TR-4CwRIT drives an internal varicap circuit, allowing plus and minus 3-4 kHz
shift, typical RIT. The RIT model is the only one with that PTO. Of course there is also a small IC controller board
as well to switch between receive and transmit, etc.

Date: 2014-01-25 22:20:58 UTC
From: Kris Merschrod
Topic: 17370 Message: 18296

Steve and Garey,

Thanks for the color codes and purpose of the PTO wires - I am almost there - the ground post was easy to recall; the signal out wire to board #1 was easy to figure out (using Garey's CD), but now I am at a loss on just where the post or lug is for the Vcc.

When I look at Board #1 I think that I see that the Vcc comes from the post just above Q4 and next to R150. Is that the correct connection for the Red/White Vcc line?

Confession - I am red/green color blind and the colors on the wires are a tad faded, but the XYL humors me and helps out.

Many thanks,

Kris KM2KM

Subject: Re: [DrakeRadio] Where to put the probe for IF and PTO freq measurements? TR-4C resusitation project

Hi All,

I've just got my TR-4C PTO on the bench. I've got:-

Black/White = Ground
Green/White = Signal Out
Red/White = Vcc (+11 volts)

Rig does show signs of having been tampered with though. Green/White wire total cold solder joint to vertical PCB underneath. Wire would spin freely in joint. So I'm guessing the radio was perhaps a little intermittent.

Some sort of grease used on PTO front end. Took ages to clean (most) of it off!

Slowly bringing her back to life.

73, Steve.

The effectiveness of any antenna is inversely proportional to the product of the ambient air temperature times the wind-speed divided by the hours being subject to the above. In common layman's terms...the colder it is, the better it works!!

The bottom end of R36 should NOT be at ground when the relay is NOT engaged. If it was, you'd have idle current in the
PA all the time.

Let me know!

I am a little puzzled by what is being discussed. If I understand the circuit the meter measures a sample of the cathode current drawn by the final amplifiers. One side of the meter goes through a switch used to change its function to RF. When set to read plate current the meter is connected though a series resistor used to adjust its sensitivity. The meter and series resistor are also across a parallel or shunting resistor R-36 which is in the line from the cathodes to three contacts on S-2. It also goes to the cathode of the AM modulator. I have tried to follow this out on the computer screen but my eye looses track. It does not appear that it can go to ground anywhere. However, its one of those places where its useful to mark up a large scale schematic with colored pencils or hi-liters. I think it might be useful to do this and re-draw the circuits through the switches in a simplified form. This will tell exactly where the circuit goes and might clarify where it could go wrong. Since some contacts on the switches go to ground its possible there is a short or bad contact there somewhere. A simplified drawing might point in the right direction to look for a problem like this. I may be missing something but I don't see how the relay could have any effect on the path to ground of this resistor. The relay has three sets of

contacts; one switches the antenna connector to either the tank circuit or the receiver connector, the second switches a ground so that in receive it grounds the mute jack to the receiver and opens the cathode return of the carrier oscillator and first mixer, which mutes the exciter, in the other position it opens the receiver mute (muting the receiver) and grounds the cathode return to the above transmitter stages. The third set of contacts connects to the cable from the AC-4 where it is looped to a connector to provide a switch for the VOX control in an L4B amplifier. Without the amplifier these contacts do nothing.
It should be possible to tell if one is getting sensible voltages at the meter by using an external meter.
The T4-XB is pretty tightly packed so a visual inspection may easily miss something. Sometimes it helps to have another person look.
Please forgive me if I have misinterpreted this whole thread.

From: <damico@...>
Topic: 18304 Message: 18304

Hello group,
my "brand new" TR7 shows a minor oddness: when I turn on the radio, the UP and DOWN buttons will not be operative, i.e. pressing them has no effect. After about 15 seconds from turn-on, they start working regularly... apart from that, everything else is absolutely ok. Since I never owned a TR7 before, I don't know if this is normal or not... if not, what could be a possible reasons? Obviously, I can live with it, it is just a very minor nuisance....
Thanks and 73,

Michele IZ2EAS

Michele, I just went to mine and up- down was available immediately.

You will see the following in print many times in regards to the TR7 & R7. This in particular if your unit has not been used for a while as in...stored. Pulling and reseating boards for a lot of different symptoms.

In your case I think.....Pull the outer cover and.....
Simply pulling off and reseating the brown pin hi/lo connector on the DR7 board could cure your problem.
Personally if you are going to do one I'd do all 5. Please be careful in the right front corner with the small power supply board that has the blue one turn pots, they are easily bumped when working with the DR7 board and a total reallignment could be the result.

Good luck, 73 Carl WD8NHK

Thanks Garey and
bookmarked it in my Drake folder. I am one of those who likes to solder!
The transformer top bolts have what seems to be enough for the stand-offs but the bottom 2 are flush with the nuts.
But they are in the right direction.

Welcome to the DrakeRadio list.!

Before you make your final decision on the AC-4 upgrade, take a look at the board set offered at Harbach Electronics
<harbachelectronics.com>.

I have used both, and the two products are of equal quality and operation, just different mechanically. You might also
check your power transformer in the AC-4. Some have the transformer bolts in the other direction or covered in epoxy
and won't accept the stand-offs of the Heathkit shop version.

A plus or minus for the Harbach version is that the PC boards are already assembled, and how much you like stuffing and
soldering boards! Some of us find that to be the best part.

Richard -

You are close! :-) The PA is keyed by the MUTE set of contacts. The grounding of this point is ALSO controlled via
the TRANSCEIVE (S2A (f & r)), and FUNCTION (S1B (r)) switches. I've never tried to trace it all the way through, but
there are multiple paths depending upon switch selections. FYI, the relay keys it via the line going over the top to
ground the cathodes of the Car Osc (via S1B (r)), IF and Mixer. That line comes down through the various switch
combinations to the line across the bottom that goes to the relay contact!

That's normal; there's a time delay, probably to make sure everything is locked.

Marco -

You could probably go with just the top two bolts, and perhaps a simple "L" bracket on one of the bottom holes. Some
have drilled four holes in the end panel of the supply cabinet and mounted it there.

Gary -

I don't think so. I have two here, and both switch immediately on power up. Nothing in the schematic to delay it.

Interesting though if yours has the same problem! :-)

Carl is likely on the right path.

As they say in the software business, that's not a bug, it's a feature. Mine does this too, and for years I thought something was wrong but never looked into it because it was only a minor annoyance. Only recently I stumbled upon a note on page 3-2 of the Owners Manual for sections I & J, to the effect that there is a 15-20 second powerup delay for the UP/DOWN buttons.

Sometimes it's surprising what you find when you RTFM.

Thank you Garey,

I just have to start to label wires with a masking tape tag and also need to take digital photos BEFORE I start pulling things apart. No power applied yet - I will report on the "smoke test" in a few days, Then the calibration of the dial.

It might have something to do with serial number ranges and if the delay was something that was added during production at some point. Might be worth looking into.

On Sunday, January 26, 2014 10:18:18 AM, Garey Barrell <k4oah@...> wrote:

Marco -

You could probably go with just the top two bolts, and perhaps a simple "L" bracket on one of the bottom holes. Some
have drilled four holes in the end panel of the supply cabinet and mounted it there.

I think it was a 'bug' sold as a 'feature' until they got it fixed~!

I don't see anything on the schematic that would account for a delay..... at least not on purpose.

Marco,
I am one of the few folks, who had difficulty with ONE of the Heathkit Shop sets. The setup is fine, and works well. My problem was that the shaft size, on the original transformer bolts, were too large for the Heathkit Shop's supplied standoffs. I committed blasphemy, by simply reversing the board, drilling four appropriately sized holes, in the end of the case, and installing it that way. It worked like a charm. But, it definitely diminishes the value of the power supply, because of modification.
All that said, I did three more AC-4's with the kit being sold at Harbach, the ES4AC4 kit. Much easier to install, works perfectly, and is a much cleaner appearance, (with the cover off) than the AC-4R kit from The Heathkit Shop. Either works fine, but, in my opinion, the ES4AC4 is the better deal by far.
BTW, the nice thing is that the designer and maker of each, are members of this list, and if you have any difficulty, they are always willing to give good advice.

Dan, after 22 years of ownership, I have no intention of ever selling my Drake. Although it diminishes the value of the PS, I'd rather have that than harm the TR-4 from lack of not taking precautions. And having looked at the PS there is leakage on 2 of the caps.

I appreciate all the help I've been getting from the group. The kit will have to wait a little longer with the holiday bills being paid off as a priority.

It's great to be in this group.

Marco

Like Dan, I too had to mount the board on the end side, due to the fact the transformer 'bolts' were on the wrong side. (If I remember, I 'believe' I uploaded pics to the pictures section) Yes, I had to drill 4 holes in the case to mount the board, but....I don't worry about losing my PS and/or the radio!! I also have another kit (ES4AC4) But haven't installed it yet.....when I decide to bring up the second 4B pair, I will rebuild its PS then.

Michele -

Don't let our kibitzing scare you off!! We really ARE friends..... :-)

There was considerable difference between TR-7s before and after around about s/n 5000 and some more in the s/n 6000
area that may account for these variations. That said, I don't think there are any REAL 'operational' issues between
the various versions. Some changes made servicing easier, others were cost cutting, and still others were just
'changes' to respond to the quirks that show up over the ~ three year production life of a product this complex. I
owned a 12xx unit for a while, and it worked just as well as the later ones.

They ALL suffer from 'connectoritis', that malady afflicting any solid-state equipment with hundreds of internal
connectors. The reliability of gold is too expensive for a product of this type, so DeoxIT and plugging and unplugging
various connectors will fix a large majority of 'problems'. Disuse is a problem also, as the minimal oxidation that
builds up on switches doesn't get scraped off unless they are rotated once in a while!

Anyway, it's a great radio, and IF it develops a problem that can't be fixed by the above there are plenty of people on
this list that are ready and willing to help.

The difference that caused the delay in early
TR7s was U9004 a Monostable Multivibrator
originally was an MC14528 in later TR7s it was
changed to An MC14538 a faster Monostable Multivibrator.
This changed the delay on the up down buttons. In
the service manual even the last printing it was
still listed as an MC14528 but the later boards had an MC14538.

Joe -

AHA! (again....) :-) It took 10-15 seconds to start??? YIKES. Or did it just wait for a power line spike to start
it up?!?! :-)

Interesting that they removed the note in the op manual yet didn't change the parts list in the sm......

Thanks!

As Garey alluded to, welcome to the world of undocumented changes. I checked two PDF owner's manuals that I have, one for TR-7 and one for TR-7A, and both had the note about the delay.

I was amused by an anecdote a ham friend related to me once. He was browsing an online shop manual web site for automobiles. There were, of course, various revisions and service notes regarding the wiring diagrams. Under the heading for "Undocumented Changes" was the simple note: "You're Screwed". Or something to that effect. The actual language may have been a bit more vulgar, but I'll leave it at that.

There has been a fair amount of work done over the years by hams documenting such changes and revisions in our radios, but new information comes to light all the time. Thanks to you bringing this question up, Joe has added another data point to the collective knowledge. IIRC I asked this same question some years ago in an online forum and did not get any useful answers.

From: Jim Shorney
Topic: 18316 Message: 18330

I still think yours is broken. The delay was created by an engineer who got kickbacks from the switch company. The idea was for frustrated hams to wear out the switches faster by repeatedly pushing them during the poorly documented delay period, thus increasing service revenue. The manual note was a red herring, everone knows that real hams never read the manual.

The strange thing is that in the very late TR7
and TR7A manual there is a note above the
description of The I and J buttons that states,
"Neither UP or DOWN frequency control is enabled
until after a preset delay time
of 15-20 seconds each time power is initiated to
the radio." The early manuals have no such note.

Subject: Re: [DrakeRadio] TR7 - HI LO delay

The difference that caused the delay in early
TR7s was U9004 a Monostable Multivibrator
originally was an MC14528 in later TR7s it was
changed to An MC14538 a faster Monostable Multivibrator.
This changed the delay on the up down buttons. In
the service manual even the last printing it was
still listed as an MC14528 but the later boards had an
MC14538.

73, Joe KC9LAD

Can a 28 be replaced by a 38 with no other changes?
Would it even be worth doing since the delay is at most a
minor inconvenience?

Garey, group,
I am not scared at all :-) I know this group well, I own also a 4C line and I have received great support from you guys in the past. I just acquired this TR7 last week from a ham friend of mine, for substantially a symbolic price, and it is in excellent electrical and cosmetic conditions... I was just wondering if this odd behaviour was a symptom of a fault, or was a bug/feature/etc. :-) Now I know and I am relaxed... thanks again, people !
BTW, I am waiting for the RV7 to arrive, then I will update the photo on QRZ.com with the new entry... :-)
73,

Michele IZ2EAS

That's how I found the difference, I noticed that
the later board had the 14538 and I had an early
board with a bad 14528 so i replaced it with a 14538 and the delay was gone.

some of my messages aren't getting through... try again

Dan, after 22 years of ownership, I have no intention of ever selling my Drake. Although it diminishes the value of the PS, I'd rather have that than harm the TR-4 from lack of not taking precautions. And having looked at the PS there is leakage on 2 of the caps.

I appreciate all the help I've been getting from the group. The kit will have to wait a little longer with the holiday bills being paid off as a priority.

It's great to be in this group.
Marco

>Marco,
>I am one of the few folks, who had difficulty with ONE of the Heathkit Shop sets. The setup is fine, and works well. My problem was that the shaft size, on the original transformer bolts, were too large for the Heathkit Shop's supplied standoffs. I committed blasphemy, by simply reversing the board, drilling four appropriately sized holes, in the end of the case, and installing it that way. It worked like a charm. But, it definitely diminishes the value of the power supply, because of modification.

OK. I assume the filaments were lit in V5 and V6?? Should've asked that a while back! If so, gotta be dead tubes.

Need to find the short on the Cathode line to the relay before installing new tubes.
Recheck front panel controls.
Should be in SEPARATE and SSB, GAIN at 0, XTALS 'Norm'. None of the others matter at this point. The bottom of R36
MUST be 'open' to ground. If not, check relay for bent contact(s), switches S1A (f&r), S2B (f) and S1B (r) for any
terminal shorting. Watch coax shields to make sure they're not touching another terminal than the one they're soldered to.

18344. TR-4C resusitation project SMOKE TEST AND DIAL CALIBRATION

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-01-27 01:35:48 UTC
From: Kris Merschrod
Topic: 17370 Message: 18344

The PTO was connected to board #1 as per Garey and Steve's help, One final check wiggling of tubes and then, THE SMOKE TEST!

No smoke, sort of weak audio, no action on the S meter, dialed up and down, heard good CW.

Dial calibration - no calibrating tone at the 100 marks - removed calibration crystal and de-oxed again. Action! then compared the dial end to end on 40 meters with the reception on the TR-4CW/rit. nice results so the PTO is direly in place and doing its job.

It is coming along but the weak audio and S-meter need attention.

One of these days the key down test will be in order, but first the reception.

That is the report on the TR-4C resustitation.

Kris KM2KM

Kris -

Progress!! Do you have plenty of 'audio' and not much signal strength (S-Meter readings), or weak audio and lots of
S-Meter??

IF you haven't already, go through and check all the hardware mounted to the chassis for tightness. Include tube
sockets, terminal strips, shield panels, & PC board mounting 'feet'.

Suggestions...

If the former:

Check the overload bulb (+12) in the relay compartment, it's socket and surroundings. DeoxIT.

Exercise the slide switch on the left rear, it must be left in the 'forward' (XCVR) position. DeoxIT

DeoxIT the relay contacts, pulling a piece of good bond paper between them.

And ...

'Rock' all the tubes in their sockets, again with a bit of DeoxIT.

Check R192, if present, for value and condition.

Check value of R92 and DC voltage on Pin 2 of V17.

Check DC values of Q5.

> Yes, the TR-4 PTO has the same FSK terminal as the T-4X. Works great for 170 Hz, or even 850 Hz shift. Thing is, it
> only shifts the frequency UP, and unlikely you could get much over 1 kHz.

Out of interest I tried this while my PTO was on the bench. Using red LED as vari-cap. I could pull up about 1200Hz for 5v.

It is easy enough to provide a constant 2.5 volts reference so that your RIT could swing up and down from a centre point but +/- 600Hz doesn't really make for as useful RIT.

You might be able to use it for Huff-Puff perhaps. But by all accounts the PTO is stable enough anyway.

Currently restoring my TR-4C. Second attempt at a smoke test in a couple of weeks at the current rate of progress.

I have been fighting this problem on my TR-7. I always get reports that I am 10 HZ low. Have adjusted all oscillators to specs and verified with two freq. counters. Is there something I have missed?

Gary K4MT

18349. TR-7 low power output

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-01-27 11:56:29 UTC
From: Jose V. Gavila
Topic: 18349 Message: 18349

Hi all,

I am working on a TR-7 with a low power output problem. But it is somewhat weird: on CW, for instance, aon 40m band, you get barely 8W with a power supply current of 15A. The situation is similar for other bands, but power consumption and power output are different on each.

I have tried to directly connect the PA output to a dummy load and then, with less power supply consumption, I get more power (i.e. 50W at 7.1MHz, with a current of 12A)

So it seems to me like a problem on the LOW PASS filter assembly, but I have looked all that area and have not located any fault.

The RX/TX relay is also working properly. I have cleaned the contacts, just in case, but the problem remains the same.

Any hint on what could happen?

Best regards,

JOSE

It takes a lot of cleaning and fiddling, but most of these rigs were working the last time they were on I've got two TR-4's that will likely need this (one will also need most of the tubes from the left side, as it was a Pepsi Syndrome rig).

The PTO was connected to board #1 as per Garey and Steve's help, One final check wiggling of tubes and then, THE SMOKE TEST!

No smoke, sort of weak audio, no action on the S meter, dialed up and down, heard good CW.

Dial calibration - no calibrating tone at the 100 marks - removed calibration crystal and de-oxed again. Action! then compared the dial end to end on 40 meters with the reception on the TR-4CW/rit. nice results so the PTO is direly in place and doing its job.

It is coming along but the weak audio and S-meter need attention.

One of these days the key down test will be in order, but first the reception.

That is the report on the TR-4C resustitation.

I am sorry bad typing it is 100 hz.

I have discovered something I need to test later. When I am using external VFO I see frequency drop by 100 hz on tx even when using the ext VFO to control TX/RX. When I switch to internal VFO this does not happen. I see the display change lower during TX while on ext VFO and verified with freq counter.

I guess I need to see why RV7 freq is changing on TX

Major pie on my face!

But before the pie - I did loosen and tighten all mechanical parts sockets etc. De-oxed the pins and sockets, also flexed the contacts and switches.

The pie - I had the slide switch on the left side in the RCVR position!!!!! Once that was correct, than you for the reminder Garey, the S-meter came to life and so did the signal strength.

The SSB was distorted but tweeking the C-130 took care of that - the manual really has nice Troiuble shooting as do Garey's CDs.

I even check the PTT and the relay does its "thing" no modulation tests yet.

So there are two of us (Steve VK2SIA) in this process - its a great hobby.

Yep - exactly.

Bought it from The Ham Shack for $75 after getting a post on this list that it was available. Cosmetically, on the outside, it's really nice. Someone obviously spilled a liquid on the left side, taking out most of the tubes on that side (they all cracked or shattered) - including the finals. There's some corrosion on the chassis, but the rig is repairable.

Google "Pepsi Syndrome" and you'll probably find the old SNL sketch with Dan Aykroyd, Larraine Newman and probably Gilda Radner. It was a spoof on "The China Syndrome".

Steve -

About what I expected..... +/- 600 Hz is pretty limited, but better than nothing I guess.

By the way, 'normal' use of the 'RTTY terminal' was a trimmer capacitor that was switched in and out by a diode, rather
than a varicap.

Don't forget the necessity of switching the RIT 'out' for transmit as part of the PTT or VOX operation!

Strange, I would have thought the same about the LP filter.

Perhaps a PA oscillation or spurious output? Direct to dummy would allow a 'non-fundamental' to contribute to the
total power seen, AND a better match. Maybe fire up the spectrum analyzer!! (Or grid dip meter!! :-))

Well, meanwhile I have done some further checks and perhaps you are right... I have used my RigExpert 200 antenna analyzer to check the low pass filters, injecting the signal on the RX/TX relay output, so they could be checked with the rig powered off. Well, all filters measured nicely!

So perhaps you are right and the PA is not generating a clean signal. I will do some checkings and will let you know what I find.

Regards,

JOSE

Check around the 'RIT Switching' circuitry on the Parent Board. The only thing I can think of that could shift the PTO
that much from receive to transmit would be the RIT circuitry, and the only obvious change is the 'source' of the RIT
voltage. The analog switches used are notorious for noise and voltage shifts.

Check the DC voltage applied to the RIT terminal on the side of the PTO when switching from R to T. If it is changing,
work your way back through the MC14016 area to see where the change is originating.

Thanks Garey:

I will do that. I find it only does it when I am using the RV7 ext VFO to control the radio. On internal VFO its fine. I connected my external DDS VFO to the radio and I do not have the problem. Maybe problem is in RV7 or voltage change to RV7. For now I will use the DDS VFO which is what I probably should use as its very accurate and rock stable.

Thanks

Gary -

OK. The RV-7 has its own voltage regulator, (Zener in the PTO,) so most likely a function of the RIT stuff. There's
PIN diode switching and the analog switches involved.

I'm betting you'll see the DC voltage on the RIT terminal (what used to the the RTTY terminal on the side of the PTO
just behind the gearbox) changing from R to T.

Let us know what you find!

Topic: 18348 Message: 18364

OK Garey. Thanks for your help. Its going to be freezing cold tomorrow so wont be able to go outside. I will get meter out and see whats up. If the RIT voltage is changing what would effect RV7 and not internal VFO. Guess I will have to dig into schematics.

That DDS VFO really works fine and I built it to allow me to do everything RV7 will do. It can do all the options of TX/RX Split etc.. I have been thinking of take PTO out of RV7 and put display for DDS under plastic front trim and make the RV7 a DDS VFO

Thanks,

Gary K4MT

Well, I'm not a big believer in all the ESD stuff. I've been using 'ESD sensitive' stuff for probably 40 years (going
back to the 40673, at least,) that were 'ESD sensitive', with no provisions other than touching a grounded object before
handling a device. I also try to hold a grounded surface of a unit as I am installing a device. Other than that,
nothing. My solder station is a Weller TCP, usually with a 700 degree magnetic, grounded tip. Work surface is Formica
and/or cardboard sheet depending upon size of unit. So far at least, no fatalities. I suppose if I was working with a
$1000 part, or a $10,000 unit, I 'might' be a little more careful, but probably not.....

Of course I don't wear silk underwear.... Had line once that had lots of ESD 'type' failures. Turned out girls
wearing silk underwear and squirming on plastic chairs were zapping things!

So..... On your IC, yes, the leads are always 'splayed' a bit. I hold them by the package ends, and place each set of
leads on the Formica surface of the bench and 'roll' the package to bring them in evenly. Do this to both sides to
minimize the amount needed on each side. I have a plastic 'IC inserter' somewhere that you push the IC into that
straightens the pins, and then a push button on top to insert it into the board. I used it a time or two, but then went
back to my own process.

Not a recommendation, just an opinion.

Garey and all,

Back in the ‘70s, Digital Equipment Corp. did a study and found that even regular TTL logic mounted on PC boards could be damaged if antistatic procedures weren’t followed. After that, they established stringent requirements for all their field service techs for handling electronic equipment. Even if damage only occurs once in a while, given the extra troubleshooting time and parts expense, I think it is worthwhile taking the extra precautions.

18367. New to group - Mystery board in TR-7

Topic: 18367 Message: 18367

Hello all - just picked up a TR-7, PS-7 and MS7 speaker a couple of days ago. The rig needed a little TLC after getting bounced around in shipping (the LED display was intermittent/dim and the power output was low) After some cleaning with DeOxit and AGC gain adjustments along with a little other tweaking, I'm back to stable display and full output power.

I also lucked out and picked up a N.O.S. Bogen MBS-510 microphone (in the box!) at the Jackson, MS hamfest yesterday that appears to be a great match to the TR-7 both acoustically and ascetically! Super bargain too.

The rig has the built-in NB and also the optional cooling fan installed. Upon pulling the covers I found what appears to be a home-brew or one-off version of an xtal-lock tacked under the main PCB. I looked on the web and couldn't find an exact duplicate of the board, and it has no markings (even the IC's have their designations wiped out) - Anyone have any idea? I'd love to find some documentation on this just in case.

Here's a link to a phone-photo showing the mystery board...

https://groups.yahoo.com/neo/groups/DrakeRadio/photos/albums/407157542/lightbox/830318380#
https://groups.yahoo.com/neo/groups/DrakeRadio/photos/albums/407157542/lightbox/830318380#

I think the TR-7 is a great rig - classic styling, tons of output, great audio reports, and a very nice PBT feature that I actually like more than the dual mode IF shift.width on the Kenwood (I think it is a little too clever for it's own good - it works, but is a bit funky). The Kenwood TS-590 will outperform the Drake under very poor conditions, but the difference is minimal and in most cases none at all. For digital modes the Kenwood of course takes advantage of the modern technology with the USB interface that makes it a perfect match for programs like HRD, but the TR-7 is an absolute joy to use for rag-chewing. It's a keeper.

Thanks

Bob -

I know that's the recommended procedure, and as I said before, this is NOT a recommendation, but my opinion. We've all
drawn a two inch spark off of a switch plate mounting (grounded) screw after merely walking across the carpeted floor in
socks! I'm sure that would do a 'number' on any unprotected semiconductor.

I always put one hand on the unit 'ground', and the other on the part in its static resistant package before handling
the part or putting the two together.

If I was working with ESD sensitive components all day long, I'd employ the mat and wrist strap process. In my
experience, it hasn't proved to warrant the time and further clutter. So Far! :-)

Hi Garey,
Well there is at least a partial success.
The IC whic has now been replaced was U9019 on the DR7. All was total blank...now I have all decimals. More diagnosis.
Original headache was my cause I had a VOM on pin 15 not pin 2. Carl

I don't recognize it, but I'd guess it's one of the earlier 'Huff-Puff' boards. It's not an "X-lock" recent version,
but might be a K4DPK (?) a considerably older version of the same idea.

I think we have a winner! Much thanks. I didn't know about K4DPK but it sure resembles the circuit board in the photo on his website (including be blacked-out IC designations).

http://home.comcast.net/~k4dpk/picture%20of%20stab.htm

My guess is that it is an earlier version of his board. Great to know!

Thanks for the quick reply.

Do you have the 'Gate Pulse' at Pin 1 of U9026.?? A scope is best, but if you don't have one an LED with suitable
resistor for 5 VDC will work in many cases. You may be able to see the slight 'flicker'. If you don't have a scope,
you may also want to consider a 'logic probe'.

<http://www.radio-electronics.com/info/t_and_m/logic-probes/logic-probe-basics.php>

<http://www.zen22142.zen.co.uk/Circuits/Testgear/lprobe.html>

Consider the operation of the counter to determine where the problem 'might' be.

You have a 500 kHz reference signal. This controls all measurement functions. From this reference, we develop a 'GATE'
pulse.

The input signal to be measured is always coming into the preamp stages and being divided by a series of decade
dividers, each with its own 'digit' of the display, resulting in the numbers just constantly 'running', sorta like the
country's 'Debt Clock'. The GATE pulse essentially 'opens' the count input for a specific time, and then closes. If
it's open for precisely 1 second, the counter will count as high as it can during that period and then display it. This
gives an accuracy of 1 Hz. If the GATE is only open for 0.1 second, it will read the same number, just with the decimal
point one step to the left, or 'tens of Hz'.

There are two key signals to start. Use your LED on Pin 4 of U9029 and Pin 1 of U9031. It should be about half
brightness (square wave). If full brightness or no light, trace back.

My Drake TR-4C is in need of a dual ganged 500k potentiometer which is used for the XMTR GAIN. Is there anyone on here with a new one, used one, or a source at which I may be able to obtain one? I'd appreciate hearing from you if you can help.

Thanks,

Lee, w0vt

I would look at Mouser, MCM Electronics or Newark. All Electronics is surplus electronics, but somes times you get lucky with what they have in stock.

18376. TR-4C crystal bank order

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-01-28 03:32:14 UTC
From: Steve VK2SJA
Topic: 18230 Message: 18376

Hi all,

Help!

Like the fool I am I pulled all the crystals from my TR-4C prior to major clean and didn't document which order they were in. After cleaning most of the crystal chassis markings have disappeared. I can see 43.6 marked closest to the LSB/USB crystal filters but none of the other markings are easily readable.

Can someone throw me a life-line and save me the trouble of reverse engineering the bandswitch just to work out where they all belong.

I do have the owners manual and Garey's service CD but can't find this information in either. No doubt because the chassis is marked so you don't need it. Doh!

Thanks!

Many thanks Garey!

It would be great if this is the only mistake I make during this restoration. Probably won't be though ;-)

Slowly rebuilding her after fairly major strip and clean. A few new replacement parts going in at the same time. Hayseed multi-cap kit, blue LED lighting, new rubber drive bush for the PTO etc, etc.

She is really starting to sparkle.

I think I need a felt washer to stop the front dial from rubbing against the dial marker perspex window.

BTW does anyone know what stops the two clear dial plates from rubbing against each-over? Is it just those two tiny plastic nibs that protrude in front of the rear most dial plate where the rear dial plate is attached to a plastic cog? Or perhaps my assembly is missing a spacer/washer between the dial plates?

I completely rebuilt the PTO. Very pleased with result. I'll swear someone used some sort of axle grease up front. Black sticky grease all over everything. Yuck!!

73, Steve.

I worked at a computer shop for 12 years and can count on one hand the number of times I used a strap. It was easy enough to lay a bare arm acoss an exposed metal area on the case before reaching inside with the other hand. That, and reasonable handling precautions with the parts/boards (i.e., don't walk across carpet, lock the cat away, etc.) seemed to be sufficient. I would often use a large ESD bag laid on the workbench as a "mat" when working on a board. These days I am required to use a strap and mat at work. I can't count how many times that strap has dragged something off the bench, or caught on something and snapped me in a sensitive spot. But it is what it is...

Interesting conversation. It has been observed that some TR-7 PAs have a tendency to oscillate in the 40-Meter segment when connected to a reactive load. The root cause has not been uncovered yet, and the workaround solution seems to less predriver gain. Adjust the PO to 100 watts via the service manual procedure for adjusting predriver gan and ALC level. A less than ideal solution, so investigation is ongoing. A PIN diode attenuator add-in that has been used by some ops to level out the drive requirements across the spectrum also seems to help with this.

I had one case where leaky driver transistors caused strange power output anomalies.

An excellent writeup on the TR-7 PA deck can be found here:

http://www.wb4hfn.com/DRAKE/DrakeArticles/TR7_Amp_Repair/TR7-Amp.htm

The wires connecting the PA deck are long enough to lift it out and lay it on top the radio to work on it. Very handy. Someone was thinking when they did that design.

I am trying to align a T-4XC, section 5-9 of the manual, Carrier Osc, Filter Match and Balanced Modulator. I am unable to derive any plate current, above resting current, with any of the adjustments described in the manual.

What I have done is loaded up the T-4XC into a dummy load and then attached an R-4C to the T-4XC with only the receive antenna connection. I then shorted the mic jack to ground and I get a S8 signal on the receiver. I rotated the carrier balance control CCW, but there is no stop at full CCW so I moved it to obtain an S meter maximum on the receiver around 20 over 9. I tuned T14, T2 and T3 for maximum S meter level. I then re-balanced the system by turning the Carrier balance to bring the receiver's S meter to the lowest value I could obtain I then adjusted C-17 to reduce the level further. I am able to reduce the signal to about S5 on the attached R-4C. I removed the short and retuned the radio for maximum output, reduced output to about 20 watts and adjusted C6 (trimmer on the underside accessible from a hole in the back panel) so that the output is exactly the same on both upper and lower sideband.

The problem that I am having is that the resultant received audio, at my local Elmer's receiver, is extremely tinny or pinched. He explains that it sounds very pinched like I am out of the filter's pass band. I am using a D104 microphone that works quite well with my TR-4Cw. I do not have this audio issue using this mic on the TR-4.

Am I anywhere close to adjusting the transmitter properly? C17 is not mentioned in the manual for this adjustment, is this to be adjusted? I need to verify that C6 is the trimmer accessible from the back panel of the rig underneath the and to the right of the carrier balance. Should I be able to null the transmitter farther that I did?

Thanks,

Doug - N9XTF

It looks like the PTT input of T-4XB that I've restored has a very high impedance: I've measured an open voltage of about -5V and a short circuit current of about -1.5uA (microamps), which means more than 3.3MOHM and makes that input sensitive to noise.
It is normal and correct or I have to find some failure?
Thanks and 73 de Guido, ik2bcp

Doug -

The problem with Section 5-9 of the manual is that it was originally written for the T-4X, which had considerably wider
filter skirts, (4-pole vs the 8-pole of the B and C versions,) and therefore you could unbalance the BAL MIX and get
drive to the PA.

Your work-around is fine, and is what I have used for many years. Just be sure you disconnect the receiver before
hitting the key in CW or TUNE!!

Two possibilities on your 'tinny' audio. Get your friend to switch sidebands with you and see how the other sideband
sounds to him. If it is very muddled and bassy, the oscillator is off frequency. If the other sideband sounds good,
then you may have a bad filter. Again, the procedure worked a lot better on the T-4X. The C filters are so much
steeper that the 'sweet spot' between them has a pretty wide 'null' area, AND the skirts are so steep that a small CAR
OSC frequency change can make a big difference. If you have or have access to a counter, the CAR OSC should be VERY
close to 5.645.000 MHz. If you have a modern transceiver with general coverage receiver, you can just listen to the CAR
OSC to verify the frequency.

Steve -

The plates are usually slightly warped, and there isn't much clearance between them. I would love to find an
'un-molested' PTO and document the exact order of washers, shims and plates on the front of the gearbox. Unfortunately,
knowing Drake, I could probably find five different arrangements!! :-)

Some have put a tiny bit of felt between the plates at the top and bottom of the discs, fastened to the chassis out of
sight. I've never had a pair that actually rubbed, but they're out there... Others have used heat and pressure to
flatten warped plates, similar to what we used to do with vinyl phono records. A couple of pieces of plate glass, a
weight and 150 degrees or so oven. Obviously easy to overdo the temperature, and I don't KNOW what the limit is. I
think I'd start with a couple of hours at about 125 degrees, and if not flat then increase temperature about 25 degrees
at a time. Don't forget to leave time for the heat to 'soak' the entire 'sandwich'. Then let cool completely under
pressure.

18388. RE: [DrakeRadio] T-4XC Carrier Osc, FIlter Match and Balanced Modulator

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-01-28 15:05:52 UTC
From: Doug Coffman
Topic: 18383 Message: 18388

Garey,

We switched between LSB and USB and both sounded the same. So I am not sure if this leads to a 12AX7 issue or possibly a capacitor issue somewhere.

Should I have adjusted C17 in this procedure? It was not mentioned in the alignment procedure. I could not null the receiver S-Meter below 5 or so with the receiver directly connected to the transmitter via the receiver antenna connection. This was the only jumper connected. Does this sound about right?

Is C6 in fact the trimmer accessible from the back of the radio on the lower right? I followed the schematic and am somewhat certain that I had the correct one.

I am new to the twins, as long as the receiver mute line is connected between the twins, there is no risk of damage to the receiver, correct?

Thanks for all you help! I will be ordering the discs for this radio set shortly. The TR-4 series was a wealth of help.

Jim -

Good point..... I've seen more than a few that were prone to oscillation of some sort, particularly on the 40M band. The
service info recommends against moving that predriver pot, implying that damage of some sort (inferred to be to the pot
itself) would result. I wonder if instead there is some 'sweet spot' in those early amps that was critical to stable
operation.

Floyd's article you referenced is the best overall reference. The PIN diode attenuator is perhaps slightly overkill, but
certainly not a bad idea.

Doug -

CAR BAL and C17, both on top of the chassis in the right rear corner, should be adjusted alternately for minimum signal.
Tune up the transmitter on 40M (or other, lower band,) into your antenna. Set GAIN to minimum, and FUNCTION to SSB.
Disconnect any microphone. CONFIRM that the GAIN control is at minimum and short the PTT to ground. The transmitter
should show idle current only, 70 mA.

CAUTION With the receiver connected as follows, it is subject to damage if the transmitter GAIN control is
increased at all. STAY in SSB.

With your receiver ANT jack connected to the OUTPUT of the T-4XC, tune in the carrier signal. Set the receiver AVC to
'FAST'. Make the adjustments in Section 5-9, para c., except only adjust R21 enough to hear a good signal in the
receiver. Then peak T14, T2 and T3 for maximum signal. Para d. should read "Adjust C6 for equal S-Meter readings on
both sidebands." Then alternate adjustment of CAR BAL and C17 should reduce that signal into the noise level.

The MUTE function of the receiver does NOT protect it from anything. It merely cuts off the IF stages. You can listen
to your signal by switching the FUNCTION switch to ON with the receiver connected normally to the 'RCVR ANT' jack on the
transmitter, with no damage to the receiver.

Yes, that is C6 on the rear panel.

If BOTH sidebands are still 'tinny' after this adjustment, you may have a problem in the mic stages, V9a and b.
Capacitor C102, (1 uF,) connected to Pin 3 of V9b would be my first suspect.

From: <kmx888@...>
Topic: 18391 Message: 18391

I was killing time and trolled through a few website of our more well known members. One of them said that he got a great deal of good from a book entitled "Basic Radio Course" by John T. Frye. The book can be hard to find as it is long out of print but I did find a paperback on Amazon. I had to look several times The price was about $15.

"Basic Radio Course" is the best book on radios that I have ever read. Most texts or articles are highly technical and go into great detail and can lose you pretty fast. For the first time this book taught me about how radios work and why in simple easy to understand language. I cannot recommend it enough to anyone that is not deeply immersed in the art of repair and understanding. It can be a bit hard to find but is well worth it.

Garey,

Thanks for laying it out That way; I wanted to make sure that I was making all of the adjustments properly. I should have it adjusted properly but I'm going to got through it again, per your example to ensure it is correct.

73,

Doug - N9XTF

I don't have a C line but will pass along experience
with a T4XB. These two have a lot of differences but the
modulator is very similar. Mine has 8 pole filters. I am
able to get the carrier oscillator centered by using an
oscilloscope on the output. A good RF voltmeter will work
as well and probably also a receiver. Unbalance the
balanced modulator as much as possible using the pot. Then
adjust the frequency trimmer (C-6 on the C) so that the
level remains the same while switching back and forth
between sidebands. I double checked this procedure by
listening to my signal on a separate receiver. The TX
running into a dummy load and the receiver isolated. I
tried this on a couple of receivers with wide enough and
symmetrical enough passbands to allow hearing either
sideband without retuning (SP-600-JX and RCA AR-88). I
found the quality was identical when the carrier was
centered as above. I don't know where C-6 is on the C but
it should not be too difficult to track it down.
Balancing the balanced modulator. There are two
adjustments and they interact. One is the carrier balance
pot and the other is a capacitor to trim out residual
capacitive unbalance. I use a receiver coupled to the dummy
load to make this adjustment. If your D-104 is on the
switch stand lock the PTT and have audio gain at minimum.
Adjust the balance pot for minimum. Then adjust the
capacitor to improve the null. Then readjust the pot. If the
capacitor is off by much you may have to juggle a few times.
The carrier suppression of the 4 series is very good and
seems to be pretty stable.
Once these adjustments are done the audio quality of
the two sidebands should be identical. If its not you may
have a bad filter. Its important to get the filter matching
transformers adjusted correctly bacause if they are not they
can also introduce some lack of symmetry in the response.
Note that the D-104 has a rather tinny sound. This is
sometimes blamed on working it into a lower than optimum
impedance but the microphone is designed to have this kind
of response. It rolls off below about 500hz and has a fairly

high rise above that. I have compared a couple of D-104's to other mics on my T4XB and also TR-4 and don't like the quality although its probably advantageous for cutting though noise. I settled on an Electro-Voice 664 based on my own listening and on signal reports. The key is does it sound the same on both sidebands?
I hope this is helpful.

My take on the predriver pot was that the caution was just related to the early version board, and was basically just because it was a cheap junk pot. I've never seen an early predriver, I suspect service took as many of them out of circulation as they could.

Bob K9JU came up with a stripped down version of the PIN attenuator that attenuates only on the low bands. I'm going to try that one out when I get a round tuit. The problem now is that this ARRL centennial W1AW/everywhere event has got me burning up the airwaves and I don't want to have the main rig offline for any length of time. I need to give the spare a tune-up and put it online for a while, I guess....

Steve:

If your dials are rubbing against the dial marker window, it sounds like your marker window is mounted on the inner wall of the inner front sub-panel as some earlier C-line models were. You can easily move it to between the front panel and the sub-panel, as later models were, by removing the front panel and mounting it to the same holes withe the same screws. There is room, and that buys you a bit of clearance for the spinning dials on the inner wall. If the dials are warped badly enough that they now rub against the metal sub-panel, place a bit of felt on each side of the dial cutout with double sided sticky tape.

Garey is right about the array of different arrangements of the dials. Some have no washers, some have one, some have two, some have three of different thicknesses....some have two brass rivets, some have three, and some have none....the latter just have two plastic posts on the rear hub gear that have been melted slightly on their tops after the dials are mounted (have only seen one like this – on an early SPR-4). I have two different thicknesses of plastic washers I keep here for dial “adjustments” as required, but admit that sometimes the use of these is limited by the length of available space on the plastic hub gear. I try to max out the space between the dials if the dials are warped with as many washers as I can fit on that hub without the Khz dial falling off the front. Later serial numbers seem to be less prone to these limitations and rarely have issues with the dials rubbing, at least from my experience with them.

John Kriner (tr7dude on E-pay) used to have some of the Drake washers available. Not sure if he has any left or not. I’ve used homemade washers cut out of yogurt container lids in extreme cases! Not my first choice obviously, but you’d never know from the front once it’s back together.

Good luck!

Subject: Re: [DrakeRadio] TR-4C crystal bank order

Many thanks Garey!

It would be great if this is the only mistake I make during this
restoration. Probably won't be though ;-)

Slowly rebuilding her after fairly major strip and clean. A few new
replacement parts going in at the same time. Hayseed multi-cap kit, blue
LED lighting, new rubber drive bush for the PTO etc, etc.

She is really starting to sparkle.

I think I need a felt washer to stop the front dial from rubbing against the dial marker perspex window.

BTW does anyone know what stops the two clear dial plates from rubbing against each-over? Is it just those two tiny plastic nibs that protrude in front of the rear most dial plate where the rear dial plate is attached to a plastic cog? Or perhaps my assembly is missing a spacer/washer between the dial plates?

I completely rebuilt the PTO. Very pleased with result. I'll swear someone used some sort of axle grease up front. Black sticky grease all over everything. Yuck!!

73, Steve.

Hi Peter,

Thank you very much for that post. Very informative!

Yes, my dial marker window was mounted on the inside of the front sub panel. I have now moved it to the front. Front dial no longer rubs here. Now why didn't I think of that?

My dial didn't appear to be touching the actual chassis but it would have been close. I had some nice black felt with a contact adhesive backing. So I cut two little rectangles out and stuck them either side of the dial window bottom edge. My impression was that tuning was both quieter and smoother by a small mount.

My PTO had no spacer washers from memory. Certainly none between the two dials where I half expected to find one. My PTO is I think, like the one you describe where the rear dial is affixed to the cog by two plastic lugs that have been melted. Front one has two only brass pins.

The two dial plates do touch (scrape against) each-over at certain points in the rotation. So my efforts so far have made a great improvement. But there is still a way to go. I'll strip the PTO back out and see if I can't work out exactly which dial is warped (probably both). Perhaps play around with some home made washers.

The thought of trying to do a controlled "melt" to flatten them out again is a little too scary for my likes.

Thanks again.

73, Steve.

Does anyone have a D-104 microphone that I can purchase to use with my Drake TR-4 Station?
Thanks
Gerald

Steve / Peter -

It's been a LONG time, but I believe the fiducial window was originally on the inside of the sub-panel. I think the
problem came about when the radio went from a single dial to a double dial. Obviously the closer the fiducial is to the
scale, the less parallax involved. Granted it's not exactly a high precision dial assembly, but.... Certainly moving it
to the outside is a reasonable approach to resolve any interference.

Heating the plates to flatten them really doesn't 'endanger' them. Polycarbonate doesn't melt until around 300 degrees
F, almost twice as high as PVC phono records (175 degrees F). Then again, I've never tried it, but I do know people who
have done it successfully.

jshorney@... writes:

The jumper board does not have a PROM, just a pair of 4050s. This is where I got confused before, The PROM on the DR-7 has nothing to do with setting the synthesizer N-Codes, that is done by the bandswitch via the digital control board. The digital control board translates the four-bit binary bandswitch data into an 8-bit BCD N-Code. With the jumper board, the N-Code from the digital control board is basically passed through to the synthesizer. With the DR-7 the N-code is clocked into a pair of preset up/down counters as the band switch is rotated to the next position. This is your "default" 500 KHz ham band segment for each band switch position. The Up/Down pusbuttons clock the preset counters up or down, which increments or decrements the N-Code to the next 500 KHz segment. The fourth bit is used via Q9001 to create the "Ham Band" (H.B.) signal to flag the transmit inhibit circuit to allow transmitting in a valid ham band (in an unmodified radio).

The late version of the digital control PCB uses a PROM to replace some of the discrete logic. I see that it uses an 82S123. This may be what you are thinking of. I've never seen one, so I have not tried to work out the "better allband transmit mod" for that board.

I am curious why you want a D-104 particularly. Be
careful when buying any crystal microphone because the
elements are vulnerable to heat, mechanical shock, and
moisture. The D-104 seems to be somewhat more rugged than
some others but the problems are with the generic type. The
D-104 has a good response for cutting through noise but I
find them a little shrill and prefer other microphones.

Kris,
That ad says modified for 4 tubes AND single band. Chances are VERY good that the single band is 11M. I've seen a LOT of them modded for multiple tubes or "hotter" tubes over the years and 11M. Sad.

From: Leon Zebrick
Topic: 18411 Message: 18411

Greetings all. I have a 6xx serial number TR-7 and I can hear myself in the speaker, low and a bit garbled. This was only a minor annoyance until I brought a SP-75 speech processor into the mix, now with the enhanced sensitivity, feedback is an issue. I assume the fix will center on installing shunt capacitance here and there, could use some specific recommendations on best placement, or any other pointers. Thanks!
Leon (N5LAZ).

John -

Possibly a bad ground on the GAIN control, second most likely is an open GAIN control, or a bad ground on R106. This is
actually a two section pot, one for TUNE (R88, front,) the other for CW (R105, rear).

In TUNE mode the transmitter is set up for SSB, and the MIC amp is converted to a ~1 kHz oscillator. This tone is fed
to the BAL MOD via the GAIN control, R88.

In CW, the 'other' section of the GAIN control, R105, is used to control a DC current applied to the diodes in the BAL
MOD, unbalancing it to allow the CAR OSC through.

TR-4C is available. Got to start working on the older ones now.

I did the alignment today and this rig was not needing much other than a slight adjustment here and there.

200W out on 80 & 40, 150W on 20 and 15 and about 120W on 10.
Receiver's just the way it should be!
Clean chassis. This one was so well-kept that I didn't need to do anything but blow some loose dust off. Small scratch on upper-right of front panel and the VOX pot has a side worn off. Has the correct mic jack. No mods and no NB. I'd say this is an 8/10.

Contact me off-list. Pics will be available as soon as it gets warm enough for me to go out to the shed again (Friday).

Wow! That is one butt ugly L-4B! Whoever did that should be drawn and quartered.

That said, there have been some elegant conversions/homebrew projects of Drake gear. Search the web for some of Ron, W2CQM's L4B conversion projects, some to 6 meters, some with 8877's in place of the 3-500's. Sweet!

One of the nicest and most unique I've ever seen was Steve Powlishen's (K1FO-SK 2012) 2 meter 8877 amp in an L-4B cabinet. Steve and I first met in 1971 – we were both 19 yrs old, and we both loved Drake gear and were die-hard VHF DX-ers. Several years later Steve had the Drake TC-2 transmit converter coupled with a C-line driving his newly homebrewed 8877 that matched in it's L-4B cabinet – WOW! Was I impressed! I built my 1st 6m 8877 just after that but it was a plain-jane rack-mount. Three 2m 8877 bamps and a 220 Mhz 8877 were completed over the years here, but never a "Drake version". I always wanted to try that approach....hmmm, retiring soon!

Steve passed away in July 2012 from a form of brain cancer, far too young at 60 years. He was a master builder, famous for his K1FO yagi designs and the Lunar-Link amplifiers. Sure would like to know where his 2m 8877 "L4B" is now. Anyone on the list know?

Speaking of elegant Drake-related projects, take a look at Lee's scope...

http://emmittsfixitshop.com/Projects_SD-7.html

Fantastic job Lee!

I'll bet it worked, all right. It probably put out lots of RF. Working WELL is
another question. That's not required for that band.

TR-4C is available. Got to start working on the older ones now.

I did the alignment today and this rig was not needing much other than a slight adjustment here and there.

200W out on 80 & 40, 150W on 20 and 15 and about 120W on 10.
Receiver's just the way it should be!
Clean chassis. This one was so well-kept that I didn't need to do anything but blow some loose dust off. Small scratch on upper-right of front panel and the VOX pot has a side worn off. Has the correct mic jack. No mods and no NB. I'd say this is an 8/10.

Contact me off-list. Pics will be available as soon as it gets warm enough for me to go out to the shed again (Friday).

From: <f6dfz@...>
Topic: 18413 Message: 18421

Hi Jim and the group,

This reflector is very and formative and friendly.

My main rig is a TR7A, but I had 4 more TR7 in the past.
I sold them, but can't live for a long time without one.
See qrz.com

All my TR7 had audio feedback, even with added decoupling of audio lines.
This is specially true with speech processing and/or high ALC driving.

Audio muting is in fact not perfect.

I use and outboard passive filter, low pass RC for SSB, and bandpass LC series centered on 500 Hz for CW.
The SSB filter get ride of the audio feedback, of the switching transient and of the high pitched noise present in the audio, due partially to the oscillator of the negative power supply.
The CW filter is wonderful and is much needed for the same reasons.
I always use headphones, this kind of filter is not really adapted to loudspeaker.

With this small help, audio is wonderful.
Of course my TR7A is aligned for a 500 Hz CW T/R offset.

Best regards.

Georges F6DFZ

>I have a 6xx serial number TR-7 and can hear myself in the speaker, low and a bit garbled. This was a minor annoyance until I introduced a SP75 speech processor - now the increased microphone circuit sensitivity is causing a bit of feedback, especially on key up. I expect the fix to involve shunt capacitors placed here and there and could use some guidance on best placement, or any other tips re this issue. Thanks!

Hey,

Well RF feedback is probably not the reason of your problem.

Please check 2nd IF/audio board schematics.
Q1113 is preamp for the audio output amplifier and get it's powersupply from either +10R or +10CW.
So Q1113 is only active during receive or in CW (to provide the sidetone audio).
In SSB mode, power to Q1113 is removed during transmit but.....C1151 still has some energy to power the preamp for a short time.
In fact the 22uF is a bit to large.
Some modifications even advise to enlarge this cap to 100uF.
Well in that case the preamp will never switch off and the SSB signal from the demodulator circuit will be fed to the audio output amplifier creating the garbled sound during SSB transmissions. And, yes, with the speech processor on, it's even worse.....

So be wise and check the value of Q1113, eventually replace it with a 4,7uF type and let me know the result.

Enjoy your TR7.

Sorry,

"So be wise and check the value of Q1113, eventually....."
should read; "So be wise and check the value of C1151, eventually....

Nice to learn from Georges, F6DF, that all his TR7's had audio feedback.
I bet if C1151 is replace bij 4,7uF, the problem is gone.

Best regards es mni DX

Wow! That is one butt ugly L-4B! Whoever did that should be drawn and quartered.

That said, there have been some elegant conversions/homebrew projects of Drake gear. Search the web for some of Ron, W2CQM's L4B conversion projects, some to 6 meters, some with 8877's in place of the 3-500's. Sweet!

One of the nicest and most unique I've ever seen was Steve Powlishen's (K1FO-SK 2012) 2 meter 8877 amp in an L-4B cabinet. Steve and I first met in 1971 – we were both 19 yrs old, and we both loved Drake gear and were die-hard VHF DX-ers. Several years later Steve had the Drake TC-2 transmit converter coupled with a C-line driving his newly homebrewed 8877 that matched in it's L-4B cabinet – WOW! Was I impressed! I built my 1st 6m 8877 just after that but it was a plain-jane rack-mount. Three 2m 8877 bamps and a 220 Mhz 8877 were completed over the years here, but never a "Drake version". I always wanted to try that approach....hmmm, retiring soon!

Steve passed away in July 2012 from a form of brain cancer, far too young at 60 years. He was a master builder, famous for his K1FO yagi designs and the Lunar-Link amplifiers. Sure would like to know where his 2m 8877 "L4B" is now. Anyone on the list know?

Speaking of elegant Drake-related projects, take a look at Lee's scope...

http://emmittsfixitshop.com/Projects_SD-7.html

Fantastic job Lee!

LOTS of ham licensees, are big time good buddies, on the CB. I never understood that. I ran a CB, from just before the mid-70's craze hit, into the 80's. Then, I got my ticket, and never looked back. But, I can say, that while I was driving truck, cross country, I did "marvel" at the junky radios, the CB crowd paid HIGH dollars for, then dumped even more money into "enhancing" them, with gadgets, that did no good. For half the money those guys would spend, I ran a Kenwood TS-570S, as my truck mobile. Even then, some of those guys ran such gawd-awful radios, and junky, class C amplifiers, that I would get interference from their transmissions on 11M, while I was trying to talk on 40.
Look, I get the fun of talking local, to a wider variety, of folks. I have a GMRS license, and have a couple of MURS radios, for talking with my wife, while I am out and about, on our acreage. But the stuff they do on CB, simply amazes me. For half the money, they could have ten times the radio, and infinite options, on various bands, if they'd just study, and get a license. But, then we'd have to deal with even more of the "10-4 good buddy" mentality. Yeah, on second thought, like the infamous 435, in L.A., let 'em have their place to play, and leave the rest of us, in peace.

From: Doug Coffman
Topic: 18348 Message: 18436

I did not look closely, it could be but unlikely, a 6M monoband chassis. Regardless, two tubes with the proper power supply reaches legal limit. I suppose one could run four tubes at legal limt with head room for high duty cycles. It’s a moot point anyhow.

What is irritating is the fact that I was working DX on 10M this morning and there were at least 4 stations, on different frequencies, operating AM and were CB operators with export radios. They can do what they want on 11M and I really don’t care; it is aggravating when they bring it up to 10M.

Hey Joe,

I actually do remember S&H green stamps as a kid. My parents collected them. Doesn't a ham guy have the deck for sale(KF2C)? That' s what I thought was interesting.

Dan,

I know several guys with the ICOM 7800’s and Yaesu Mark V field radios that operate 11M only. They do not have tickets and operate CH38 USB. What a waste of good and expensive equipment!!!

We can all bash 11M but I have hear a number of conversations on 80M and 20M that rivals the best of the junk on 11M. I just wonder how these people conduct themselves in their work and family lives!

Subject: Re: [DrakeRadio] L4B with four tubes!

LOTS of ham licensees, are big time good buddies, on the CB. I never understood that. I ran a CB, from just before the mid-70's craze hit, into the 80's. Then, I got my ticket, and never looked back. But, I can say, that while I was driving truck, cross country, I did "marvel" at the junky radios, the CB crowd paid HIGH dollars for, then dumped even more money into "enhancing" them, with gadgets, that did no good. For half the money those guys would spend, I ran a Kenwood TS-570S, as my truck mobile. Even then, some of those guys ran such gawd-awful radios, and junky, class C amplifiers, that I would get interference from their transmissions on 11M, while I was trying to talk on 40.

Look, I get the fun of talking local, to a wider variety, of folks. I have a GMRS license, and have a couple of MURS radios, for talking with my wife, while I am out and about, on our acreage. But the stuff they do on CB, simply amazes me. For half the money, they could have ten times the radio, and infinite options, on various bands, if they'd just study, and get a license. But, then we'd have to deal with even more of the "10-4 good buddy" mentality. Yeah, on second thought, like the infamous 435, in L.A., let 'em have their place to play, and leave the rest of us, in peace.

18439. Meter Specs

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-01-30 16:42:39 UTC
From: <kmx888@...>
Topic: 18439 Message: 18439

I have copied the note below from Ram Meters. What do you think about the slight difference in meter resistance and the idea in general?

Hi Kevin,

Thank you for the information below. The Jewell MS2T is no longer available. I tried to find a meter that was close in size and found the Yokogawa 251-2. I attached the dimensional sheet for your review.

The Jewell meter measures 3.15" x 2.73" and the panel cutout is 2.22".
The Yokogawa measures 3.12" x 2.66" and the panel cutout is 2.19"

The Jewell meter is a 3-stud mount and the Yokogawa is a 2-stud mount. Also, the resistance for the 251-2 at 200uADC is 121 ohms. If you think this will work as a suitable replacement then I would need a picture of the face of the meter so we can try to duplicate it.

Please let me know your thoughts.
Thank you and have a nice day,

Steve -

No problem posting prices for items offered for sale. I also have no problem with hams supplying the market with
specialized products for the community, 'within reason'. We don't want a 'for sale' reflector, but if someone has a
product or products of interest to many of us, an occasional 'announcement' is fine. Once a month maximum?

Kevin -

The new meter isn't big enough to cover the panel, which may or may not be significant.

A new scale.

The meter is connected as a voltmeter with a series limiting resistor, so the internal resistance isn't critical, within
reason.

73, Doug – N9XTF

The real problem is that there is absolutely no enforcement. The CB bands are nearly impossible to police but the ham bands are not. I hear stuff every day that could result in large fines or even jail time. The same folks doing it week after week. Of course, when I first went on the air in the 1960s we had exactly the same kind of jerks and no enforcement but just not as many of them. 11 meter CB was one of the world's great blunders.

Hi Henry and the group,

Interesting tip, we shall wait for results.
But I notice that the feedback is not a burst, but can be permanent.
So it's unlikely that the charge of C1151 is the culprit.

I frequently thought of a way to more efficiently mute the TR7 during SSB transmit, but, with my small filter,
I found an outboard solution good enough to suppress the problem.

Georges

On the ARRL website it says that the FCC rules prohibit willful interference with ANY radio communication or signal:

"Section 97.101(d) of the Commission's Rules prohibits amateur operators from willfully or maliciously interfering with or causing interference to any radio communication or signal. 47 C.F.R. § 97.101(d). "

Of course on 10m you could always say you never heard them .....

Topic: 18413 Message: 18457

I tend to agree. The aggregate time constant of the circuit with a 22uF capacitor is under 5 seconds. Unless you are running a contest or calling a pileup, the feedback would cease after a short time of keydown.

An argument for increasing the value of the capacitor is to improve decoupling and reduce IMD in the audio stage. Bob K9JU discovered that preamp stage has rather high IMD. I would rather have low IMD than not....

From: Leon Zebrick
Topic: 18413 Message: 18463

In my case I get about one second of feedback that goes out over the air at about 40 W pep. That's if my SP75 is on and my mic is anywhere near the remote speaker. My gain is set to reliably break the SP75 noise gate and modulate the rig with the right amount of ALC. Mic is a Shure 444. So if preamp power does not bleed off in less than one second, I'm thinking the cap mod won't help. Perhaps voltage bleed down will be fast enough? After that short feedback burst I can still hear garble in the speaker, but it's low and I can live with it. Just want to stop announcing my key up. Tried vox but not enough vox gain - project for another day.

Mark -

I'm not familiar with that keyer. The T-4X is a negative key voltage of about -60 VDC, and takes only a mA or so to key.

As long as the output is capable of keying a negative voltage, should be no problem.

Hi to the group,

I get also great improvement about feedback with a double line between the TR7A power plug (heavy gauge for the PA, lighter for other stages) and with clean contacts on this same power plug (I use Deposit). I also use some piece of plastic cards inside this power plug to get tighter contacts.

These simple actions have a great effect on feedback.

I couldn't remember the exact voltage, so figured allowing for -110 would be sufficient. Feels just as annoying when it bites me...

Mark -

I'm not familiar with that keyer. The T-4X is a negative key voltage of about -60 VDC, and takes only a mA or so to key.

As long as the output is capable of keying a negative voltage, should be no problem.

Not sure what is going on there. I've never seen that behaviour from my SP75 and TR-7, and I've used a number of different mics and speakers with this combo. It does sound more like RF feedback to me. You might check your 2nd IF/Audio board, there have been some revisions to it over the years in the area of T/R switching. I have detailed some of that here:

http://radiojim.exofire.net/pages/TR7_2IFA.html

On another note, I recommend running the level with the SP-75 at just below the point where the ALC light begins to flicker. This will give you the cleanest possible signal. The logic for staying out of ALC is based on information found here:

http://www.sm5bsz.com/dynrange/alc.htm

You should also be speaking no more than about inch away from your mic. The farther away you get, the more gain you need and the lower your transmit S/N ratio becomes.

>In my case I get about one second of feedback that goes out over the air at about 40 W pep. That's if my SP75 is on and my mic is anywhere near the remote speaker. My gain is set to reliably break the SP75 noise gate and modulate the rig with the right amount of ALC. Mic is a Shure 444. So if preamp power does not bleed off in less than one second, I'm thinking the cap mod won't help. Perhaps voltage bleed down will be fast enough? After that short feedback burst I can still hear garble in the speaker, but it's low and I can live with it. Just want to stop announcing my key up. Tried vox but not enough vox gain - project for another day.

From: <wd5acp@...>
Topic: 18469 Message: 18469

Hello all - new to me TR-7. I did a search here but missed anyone having this issue... my TR-7 audio does volume control does not reduce the volume all the way. Even when turned down to minimum, there's still low audio from the speaker. I can decrease the RF gain and effectively silence it, but if the RG gain is up and there's any noise or signals on the frequency it is clearly audible.

Not a show stopper, and probably not worth tearing the radio open to fix it, but just thought i'd ask if anyone has had this issue before.

The volume control works fine in every other respect. Full audio when turned up. No noise, not scratchy. It was shot clean with a good dose of DeOxit5 recently and that didn't help.

Thanks!

Guys.

A few years ago I came out with a small ,about the size if a quarter, pcb that would key the grid block keying on the drakes or the cathode keying for some of the other rig. Used an optical coupler to connect a keyer to the rig. I used a cw keyboard connected to my drake 2NT. Great fun!

I may have one or two floating around the shack. I'll look.

This is a known, and normal condition. Because of the design of the taper, the wiper does not go to zero resistence because it has been advance several degrees due to the on/off switch being activated.

Hi Guys,
A friend of mine G4ALH has for the 3rd time had a Failure with the 50watt Bleeder resistors in the PSU.
I have a L4B, and touch wood, I have never had a problem with them.
Is this an issue with the PSU's or an isolated case.
We are wondering if there is something else that maybe causing this problem.
Any idea's??

Keith,

Having serviced L4, L4B, and L7 amplifiers, and remembering they can be 30-40 years old, I have found the failure rate of those resistors to be around 60-70%. While that might seem high, remember the age and the variability of the operating environment. When those resistors are replaced, and both should be done at the same time, the 5 K 7 watt resistor on the underside should also be replaced with a 20 watt equivalent. To me, a large contributing factor in addition to age, is the heat within the power supply. In rare instances, there might be a flashover to ground between the end region of the resistor(s) and the triangular metal mounting "flanges"; the through bolt design doesn't seem to be prone to the arc-over and one can always switch to epoxy-fiberglass triangles for mounting when in doubt. Hence, I either use and internal fan (lots of work) or an external fan or fans. What works well is a 220 v fan that is selected on the basis of starting and running reliably one 110 vac. Then, with a thin rubber foot under each corner, you get some cooling (by pulling air OUT) and it is virtually silent. Based upon my measurements with my non-contact IR thermometer, such an arrangement results in a case temperature drop of 30 deg F.

I'm sure there are some experts out there that can give you better advice and better explanation than the above so let's all share and we can all learn.

73,

Evan, K9SQG

Split rail power feed is perhaps the best kept secret of the TR-7. It's a great idea from an engineerig standpoint, but almost no one talks about it. GW4ALG mentions it on his mods page, and I write about it occasionally only to usually be met with thundering silence.

I've done it with both a "generic" power cable and as a retrofit to a PS-7 and am very happy with the results. This radio is designed to produce 150 Watts PEP or CW output with finals that are 50% efficient at best, which means the peak power draw can exceed 300 Watts. You can do the math. I have seen some pretty wimpy after-market generic cables on the market. I don't think I have seen one yet that I would buy. The PS-7 stock cable seems adequate for the high current rail. I used primary wire from a GE Mastr II harness, the stuff they use to trunk-mount 100W FM mobile radios, for the generic cable. I don't know what guage it is, but it's robust. No need to skimp on the low current rail either, use at least #14. You should see little or no lamp dimming from zero to full power with a proper cable.

Keith -

Evan (as usual) has the right info! Heat is the killer and a simple (silent) fan with rubber feet set on top of the
cabinet over the center, _blowing UP_ does wonders for the supply longevity.

Problem solved. Did change the 22uf cap on IF/Audio to 4.7uf but that had minimal influence, will leave the 4.7 in for good measure. No degradation in audio quality noted. While the case was off I started playing around with a .01uf on speaker jack, etc. That didn't help, but while testing I noticed that with the mic near the PA, severe feedback occurred. I opened the Shure 444 and tacked that .01uf from the audio hot to gnd. and that did it! Thanks all.

From: Joe Pyles
Topic: 18469 Message: 18480

I have fixed this on Several TR7s, The problem is
not that the switch causes the wiper to not go
all the way down. The problem is that the end of the carbon
goes out to the crimp on terminal on the pot and
the wiper doesn't stick out far enough and when
you turn the pot all the way down the is a small space between the
wiper and the terminal it only amounts to around
10 ohms but that is enough to allow sound to be
heard. To fix the problem I had to disassemble the pot and bend
the outer contact of the wiper out so it contacts
the outer edge of the carbon and when all the way
down it will it will be closer to the terminal and the resistance
will be 1 or 2 ohms. I worked for General
Aviation Electronics (Genave) in the 70s and we
had the same problem with the CTS pots that we used.

From: Jim Shorney
Topic: 18413 Message: 18481

That's interesting, because one of the mics I have used with no issues is the Sure 444B. I was getting severe RF feedback in my Telex aviation headset at one point. I discovered a disconnected cable shield inside the can. I suspect there may be more to your problem. The TR-7 and SP-75 may also suffer, to some degree or other, from the "Pin 1 Problem". I modified my pair for direct shield-to-chassis ground when I was troubleshooting the headset.

http://www.rane.com/note151.html

It may not seem obvious, but this can also apply to unbalanced mics on HF transmitters.

http://www.heilsound.com/amateur/tips/131-rfi-removal-from-audio-inputs

If you look at both the TR-7 and the SP-75 the mic cable ground/shield does not ground directly to the chassis, but through a length of wire to the circuit board.

Also worth noting is that some operators have reported that, despite what the SP-75 manual says, they need a ground strap from the SP-75 chassis to the TR-7 chassis.

Hey Leon,

The same happened in my TR7 sn 6348.
Just change C1151 from 22uF to 4.7uF and the symptoms disappear.

Vox gain to low, on the transmit exciter board, change R325 from 100k to 200k.

Subject: Re: [DrakeRadio] L7 linear problems

Keith,

Having serviced L4, L4B, and L7 amplifiers, and remembering they can be 30-40 years old, I have found the failure rate of those resistors to be around 60-70%. While that might seem high, remember the age and the variability of the operating environment. When those resistors are replaced, and both should be done at the same time, the 5 K 7 watt resistor on the underside should also be replaced with a 20 watt equivalent. To me, a large contributing factor in addition to age, is the heat within the power supply. In rare instances, there might be a flashover to ground between the end region of the resistor(s) and the triangular metal mounting "flanges"; the through bolt design doesn't seem to be prone to the arc-over and one can always switch to epoxy-fiberglass triangles for mounting when in doubt. Hence, I either use and internal fan (lots of work) or an external fan or fans. What works well is a 220 v fan that is selected on the basis of starting and running reliably one 110 vac. Then, with a thin rubber foot under each corner, you get some cooling (by pulling air OUT) and it is virtually silent. Based upon my measurements with my non-contact IR thermometer, such an arrangement results in a case temperature drop of 30 deg F.

I'm sure there are some experts out there that can give you better advice and better explanation than the above so let's all share and we can all learn.

Hi Guys,

A friend of mine G4ALH has for the 3rd time had a Failure with the 50watt Bleeder resistors in the PSU.

I have a L4B, and touch wood, I have never had a problem with them.

Is this an issue with the PSU's or an isolated case.

We are wondering if there is something else that maybe causing this problem.

Any idea's??

>Vox gain to low, on the transmit exciter board, change R325 from 100k to 200k.

Another way, from DrakemodV6:

"The VOX requires about 50 mv of microphone input to trigger reliably from pin 1 on the mic connector. On the TR7, it takes a very high setting on the VOX Gain control to make the VOX trip. This is in contrast to the mic gain, where not much is needed at all. C304, a .01 uF capacitor coupling the voltage doubler has a reactance of 15K at 1 kHz. Its value is much too low, especially when the applied mic input signal is divided in half by C320, another .01 (transient suppression). Change C304 to a .1 uF. The improvement is such that it will take barely adequate VOX gain to 'acceptable'. "

I did this and almost have too much VOX gain now. A value between .05 and .1 might be optimal for my rig. YMMV.

Garey and the others that were kind enough to reply to my request for help below:

Thanks - I ordered the C-129/C-140 cap from Hayseed Hamfest, installed it in the T-4XB and the problem is solved.

Now to move on to the T-4XC .. thanks so very much ... what a great source of information.

73, Michael NZ4D

==========

Michael -

Almost certainly this is the electrolytic cap (C129 T-4XB) or (C107 T-4XC). You can check by connecting a good cap in
parallel with each of these.
Replacement cap(s) available from Hayseedhamfest.com.

Secondary possibility is the switching diode (D8 T-4XB) or (CR15 T-4XC). Check voltage across diode. Should be -0.7
VDC or so key UP, and +15 VDC or more key down.

If no luck, check back here!

Hi Y'all,

I've looked at the manual for the FS-4 and didn't see anything...

What should the injection voltage out of the FS-4 be going into the R-4?

I see the June 2004 article by Steven Hageman shows he was getting about 2 volts P-P using a 50 ohm load out of his crystal eliminator. Does that sound about right?

A question for someone more knowledgable than me (just about everyone :-).

The neutralization method Steve describes where you temporarilly disconnect the screen voltage (+250) to the PA cage.

Can this be safely done in the power supply? Or are other parts of the circuit dependent on the presence of +250v?

I've done it right at the base of the tube (tubes if running two finals) on the tube socket. Be sure the wires aren't close to anything else....and in some cases, I've put a 'pinch' of black electrical tape on them while doing the neutralization.

Steve -

I don't think so. You need the +250 to pull in the T/R relay. You could manually close it, if it's the TR-4, but
difficult with the later 'ice cube' relays. I guess you could just temporarily ground the XMIT bus at the 'bottom' end
of the meter shunt resistor.

I disconnect just outside the underchassis PA shield, unless it has the 'VHF Mod' when you can just pull the jumper
cable. Disconnect from the outside of the ceramic bypass feedthrough. Careful, they ARE breakable, and don't like
'side loading'!

May work, if you try it let us know!

Topic: 18076 Message: 18493

Steve,

The screen voltage for the final tubes is supply from the power supply through "pin 11". If you disconnect the voltage in the power supply to pin 11 you will effectively accomplish the desired effect, remove the screen voltage from the final tube BUT you will also remove B+ to other stages/tubes as well which you do not want to happen.

You can see this by reviewing the power supply (AC3 or AC4 it doesn't matter) and the transmitter power connector pin 11. The power supply and transmitter schematics are in the transmitter manual or you can purchase Garey, K4OAH, Drake CDs and they are included on the CD.

http://k4oah.com/

I agree, disconnect the screen voltage at the tube socket, not at/inside the power supply.

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

73, Garey - K4OAH

Jim,
Check the archives of this list for 'restorations', or check the files section for the same. In a nutshell...replace the filter caps in the power supply as it is not a question of "if" they are bad but rather "when" they'll go bad and take out the transmitter. While you're at it, replace all paper and bumble bee electrolytic caps, check all resistors to make sure none have gone way high on you (more than 10% of spec'd value). Once those have been changed out, then clean all switch contacts using a cut down cotton swab with a drop of DeOxit on it, making sure you leave no "fuzz" behind. Check the tubes with a reliable tube checker. Then power up the units using a Dim Bulb protector...(look up dim bulb test) which is an ordinary light socket in series with the hot lead of the 117 V AC cord, using an AC socket into which you plug in the trans/receiver. From that point, you'll know if it works or not (don't forget to connect a piece of wire about 14 feet will do, or connect to a ham antenna to receive. On transmit first power-up, best to go directly to a dummy load. You may need to do an alignment also.

Then you can concentrate on cleaning, dusting, renewing the 'looks'. Personally I do very little cleaning until I know the
dang thing is going to work. Others may do things differently...this is just my way. Of course it has been advised over and over again that one should not just 'hose down' the switches with electronic cleaner, because some wafers will absorb the moisture-liquid and swell, throwing all contacts out of alignment....a bad deal. Some have hosed their chassis down with scrubbing bubbles, left them sit for awhile, then washed them off with the shower. I would sure hesitate to do that, as I've only heard of that being done on some Hallicrafters models. Good luck. Keep us posted.

Jim -

1. Check for the correct fuses (0.75A R, 5-1/4 T). If they show signs of dampness, I'd give them an hour or two in
direct sunlight or in a cardboard box with a 100W light bulb.

2. Go through with a screwdriver and tighten all hardware, tube sockets, terminal strips, PC board 'feet', shield
panels. Carry out careful inspection as you go for any obvious electrical or mechanical damage.

3. Put a 40W light bulb in series with the line in and turn them on. If the light flashes brightly and then dims
almost out, (most likely,) they're fine and let them run for an hour or so 'under observation'. Then take out the bulb
and go!

4. If the bulb STAYS bright, you probably have dead electrolytics and/or power supply diodes. Fix as needed.

5. Run an alignment check, check all switches and knobs for function. Fix as needed.! Give all tube sockets switches
and other connectors a DeoxIT treatment. DO NOT _SPRAY_ anything, use a Q-Tip for stubborn stuff. Use FaderLube on pots.

6. The other extreme is to measure each resistor, replace all the electrolytics and film capacitors, resolder all the
connections, and THEN go back to #1.

It's less work to disconnect at the feed-through. You just have to have a light touch with the soldering iron. I've never broken one - you just need to not press too hard on it and not overheat it.

A question for someone more knowledgable than me (just about everyone :-).

The neutralization method Steve describes where you temporarilly disconnect the screen voltage (+250) to the PA cage.

Can this be safely done in the power supply? Or are other parts of the circuit dependent on the presence of +250v?

Everyone here knows I'm a "washer". I don't always, but from your description, these sound like good candidates for that. See previous posts.

As Bernie mentioned, I do make sure I get the rig working at least to the point where everything is functioning - even if the whole rig is out of alignment. Replacing components prior to cleaning allows extra cleaning around the new parts (such as excess flux).

I remove the tubes and PTO's before doing the wash, and I do NOT dunk!

Wayne -

You probably have hum on SSB as well, but it's so far down the filter skirt it's not audible.

I'd start by bridging C107 with a 60 uF or more cap. If that clears it up, see Hayseedhamfest.!

If not, lemme know!

After more investigation, turns out more than just hum. something is pulsing at 60 hz. In AM mode, listening on another receiver can hear the pulse, have pulsing RF output. In SSB mode, U/L doesn't matter, have hum but not the cycling. Now I know why the bad signal report!

Probably the 'controlled carrier' effect of the AM. Could be a bad V9, but I'd start with the cap.

You were right again! C107 was bad. Installed the Hayseed Hamfest replacement can.

Had me worried when I attempted to tune up and had no drive. Suspected V9. Changed it out for NOS and all is well. Hum gone. Nice clean tone from carrier.

Thanks again!

18510. AC3 and 240 volt AC mains

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-02 23:54:48 UTC
From: Steve VK2SJA
Topic: 18076 Message: 18510

Thanks everyone.

I understand now. While rebuilding the second attempt at a working power supply (AC3) I was idly thinking about adding a separate +250v fuse. Easy disconnect. But as I somewhat guessed this is not practical as the radio requires +250v for lots of things.

Even getting the correct voltages to the rig in Australia is proving more difficult than one might expect.

The first AC3 power supply I purchased had a transformer with only one 110vac primary winding. So it could not be modified for 240vac operation.

The second AC3 has the correct transformer with two primary windings. Windings are in parallel for 110vac and series for 240vac. The colour coding in the AC3 manual for the phasing of these windings was incorrect for my transformer BTW.

But even after I got the windings sorted out I'm rather convinced that this transformer really wants 220vac. And not the 250vac that I've got on my wall outlet. We are officially 230vac in Australia since 2000 (it was 240vac previous to 2000). 250vac however is *just* inside the allowed spec and not uncommon for certain parts of the country closer to power stations.

I brought the AC3 supply up on a variac looking at the voltages. At 220vac supply all the outputs look bang on the money. And the transformer is *just* starting to make a comfortable I'm alive hum, barely audible. Increase the supply to 250vac and the hum takes on the ominous growl that one normally associates with "Danger Will Robertson". And all the supply outputs look uncomfortably high (admittedly there is no load at this stage).

I guess that the radio (TR-4C) and PSU might run at the elevated voltage levels but I suspect that it won't do much for the longevity of either.

So it looks like I'm going to have to create a permanent auto-transformer arrangement to lower the mains voltage back down to 220vac.

I'm thinking to try build one of these:-

http://archive.siliconchip.com.au/cms/A_112364/article.html

Anyway, mostly I'm just posting for posterity in the hope it may help someone else down the line who is trying to do the same thing. But any advice and guidance is always gratefully received!

73, Steve.

Greetings, I just purchased a T-4XB and a R-4B. I am a first time Drake owner so been searching the messages here for info. I have a few questions.

1.Looking at my R-4 I noticed that some caps need replacing. I see several people selling replacements so that is nice. However, the installation looks to be sporty. If one of the small boards needs to be unscrewed from the frame, is there enough give in the hookup wires to move the board a little bit or do you have to unsolder the wires to get at the cap.

2. I noticed that my S meter on the R-4 doesn't move at all. It comes up from 0 when I turn it on but just parks at 9 no matter if I tune to a strong or weak signal. I see the adjustment procedure in the manual but was wondering if there was any other tips to try.

3. The cinch jones connector that plugs into the T-4XB seems to have an extra wire sticking out next to the RCA connector. It is just a short wire with some electric tape wrapped around it. Not sure what pin it is hooked up to. Don't see it in the schematic so was wonder if this was some common mod.

Thanks

Mark

Steve -

I don't see a price for the product you mention. All you need is a filament transformer with a secondary voltage equal
to how much you want to reduce the mains, and capable of handling the 3 Amps drawn by the power supply. Put the primary
across the mains, and put the secondary in series with the primary of the AC-3 transformer. Arrange the leads so that
the filament voltage is 'out of phase' with the AC-3 primary, and you're done.

You can find a drawing for this as a 'boost/buck' transformer connection all over the internet.

Mark -

Both the manuals are on your CD (went out yesterday via First Class Mail..)

The recap kit from Tom at HayseedHamfest.com is the simplest approach.

The RF GAIN control must be full CW for the meter to work. You need a shorting plug in the MUTE connector on the back of
the receiver for it to operate in any but the ON position of the FUNCTION switch. When this is done, with no signal or
antenna just adjust the ZERO control on the side to see if you can set the meter to zero. If not, check and make sure
that all the tubes are in the correct sockets, and that they are all 'lit'. XTALS switch must be in NORM position.

It looks like a simple receiver, but the controls must ALL be in the correct position for it to work. Section 4 of the
manual explains......

Hey Garey;

Good deal on the CDs. I thought I had all the switches in the correct spots but did not give the tubes a real close inspection so I pull the top off the R4B and pulled the tubes (well, not the one in the metal sleeve) to make sure the correct ones were in the proper socket. Reseated the tubes, shorted the mute, dimmed the room lights and switched the radio on.All the tubes lighted up and I zeroed the meter. Hooked it up to the T-4XB and meter works great. If only the cap change should go so smoothly.

Thanks

Mark

Hi Garey,

Thanks for the suggestion!

The page I linked is not a product as such but a construction article from Silicon Chip magazine. Many of the construction articles they print wind up being sold as "electronic kits" by various electronics stores. But not this particular one as far as I know.

The article describes how to build what I believe I am correct in calling an auto-transformer. They used a fairly common garden variety transformer with multiple voltage taps on the secondary side. Then interconnected the primary of the transformer with the secondary in series. Using the "tap" points on the secondary to arrive at your desired output voltage.

The article does make note that you are supply limited by the current handling capability of the secondary.

The page I linked only contains the introduction to the article. They want you to pay for the rest :-) The details regarding the transformer used are on subsequent pages. But the all important circuit diagram is on the first page.

Solving the problem with a "boost/buck" transformer as you suggest seems a very similar solution. A very important difference appears to be that with the boost/buck arrangement you describe, that the "killer" mains voltage is all kept isolated on one side of the transformer(s). Which is not the case with the auto-transformer. Obviously having this extra isolation would be desirable. The Silicon Chip solution to the problem means that you wouldn't have to mess with the internals of your appliance. A non issue in this case.

I have ordered a reasonably cheap (multi-tap 12-30v 120VA) transformer that has a 30 volt 4 Amp secondary output. It would appear that I could use this in either configuration.

73. Steve.

I acquired a beautiful 2-B receiver from the collection of Sindre Torp, LA6OP, a noted Drake collector.

Of course, it's wired for the EU standard.

How would I re-wire it for US operation?

The cap change is fairly simple if you have the right equipment and are comfortable around soldering.

Yes, there's one board that's close to the cap and you can move it some if you need to. A couple of other tips, from experience:

1. Take a couple of photos of the wiring to the cap. Even if you don't use the photo afterwards, it's peace of mind.
2. Cut the wires at the capacitor tabs. The insulation on these wires melts extremely easy and you'll wind up with a wire end that looks like it was painted by Salvador Dali, otherwise.
3. Per #2, if the wires are now too short, splice in a short length of new hook-up wire, soldering multiple original wire-ends to the far side, and fitting a piece of shrink tubing over the splice. This happens most often with the red-striped wired. USUALLY, the others will be fine.
4. I believe Hayseed provides a new resistor but if they don't, get a new one and don't try to re-use the old one.
5. It's easiest to cut the grounding tabs off the old cap, then melt the solder around the tabs to remove them.
6. This is where the "correct equipment" comes in. Don't even try to solder the grounding tabs with a 35W or smaller pencil iron. You need at least a 100W iron (Mine's called "The Cattle Prod") or gun to flow the solder between the chassis and the new cap.
7. When re-soldering the wires, remember #2. Just enough heat to flow the solder and make a good joint. Don't touch or move the wires until everything has cooled down.

Good luck. It's really not a bad job once you know what you're getting into.

73,

Steve Wedge, W1ES/4

Jim -

A couple of wires on the transformer primary need to be moved. The color codes and connections are shown on the schematic.

There's a nice color photo of the leads and the provided terminal strip in my CD (:-)) but the schematic is all you need.

Let me know if you need more help!

Steve -

OK. Yes, the principle is the same. You don't have to get inside the AC-3 this way either. Connect your 'new'
transformer primary to the mains, and put the secondary in series with the line cord to the supply. ALL external. Best
to put it in a box of some sort to keep fingers out, but just a standard wall outlet on the box to plug the AC-3 into.

One caveat.... When you start, be aware that if you connect the external transformer up incorrectly, it will BOOST the
line voltage by the same amount! Be sure to check the output connector before plugging in the AC-3. If you get 250 VAC
(!), reverse _either_ the primary -OR- secondary connections of the external transformer.

Above all ** BE CAREFUL **.

18521. "Hacked" R-4A's and FleaBay

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-03 15:06:44 UTC
From: Steve Wedge
Topic: 18348 Message: 18521

Yep - we all have to remember that before these became collectible, they were pressed into service by hams who got them cheap because they were "old" or "obsolete". My first decent receiver in 1983 was an old R-4A that was dusty and crusty but started working well again after I cleaned the bandswitch contacts (I have to admit to using an eraser and "contact cleaner" back then :-o)

"Hacked" rigs can still be made to work as intended again, but you have to decide if some extra holes are important to you or not. Because I try and find restorable/fixable rigs to make some extra money, I tend to shy away from anything that had the chassis hacked. Front panels and covers can be easily replaced, with patience in waiting for them.

I looked at what the current bid is on this set and decided it probably would take too much work and parts. However, it will be a great deal for some of the folks on here who are limited in their ham budget.

I would point out to anyone looking in this range, that there's also a fairly decent R-4 with about the same amount of time left on the clock. I have found the R-4 to be the equal of the 13-tube R-4A, with the exception of the lack of vernier drive for the preselector. The 6AU6 PTO tube does a great job with sufficient warm-up time and really isn't bad from a cold start, truth be told. You can install a Jackson Drive in the R-4 if you drill one 3/16" to 1/4" hole in the chassis to mount the drive and cut off the existing shaft to accommodate the new drive. I have an R-4 right now that had this done and it's a good enough job that it may have been done by the factory. The R-4 in this auction also has quite a few auxiliary crystals and a B-Line PTO knob.

http://www.ebay.com/itm/Drake-R-4-Amateur-Radio-Receiver-/181313332920?pt=US_Ham_Radio_Receivers&hash=item2a371de6b8

$40 to ship to NC, so at almost $110, there's not enough "meat" on it for me.

Subject: Re: [DrakeRadio] L4B with four tubes!

I'm all for experimentation, upgrades, improvements etc. but I absolutely hate to see people Jury Rig anything, especially one of these radios that so many work so hard to restore or preserve. Take a look at the speaker addition to the R-4A on EPay http://www.ebay.com/itm/Drake-R4A-HAM-Radio-Receiver-For-Parts-Or-Repair-/201028701269?pt=US_Ham_Radio_Receivers&hash=item2ece3e8c55 This one really makes me cringe.

Mark -

Cool! Always nice when one 'wakes up' after a successful repair.

The cap change isn't particularly difficult. If at all possible take pictures of the area before you start. (Or you
could buy my CD!) Plus write down the color of the wires attached to each terminal. Note the identifiers cut into the
terminals on the new cap and be sure to orient the new one the same way. Best to cut the wires from the old cap as
close as you can to the terminals, rather than try to desolder them. The insulation on the wire used by Drake is
extremely heat sensitive, so you want a hot soldering iron so you can solder the new connections as quickly as possible.

The film caps C109, C126 and C163 rarely fail, and don't need to be replaced until they do, (if ever!) ALL the
electrolytics should be replaced and are in the kit from Tom.

Keep us informed as to how you are doing, and don't hesitate to come back for more encouragement if necessary!

Just thought I'd let y'all know that Hayseed Hamfest is running on schedule again! Don't let the notice on their website put you off (and I've let Tom know he should change it).

I ordered a 2-B kit on Saturday and it was in my mailbox today!

I ordered and got a cap from Tom a few days ago. Came
in a couple of days. This a filter cap for an HQ-129-X.
BTW, it is surprising how many odd symptoms a bad filter cap
can cause. People think its just a lot of hum but bad
filters can also cause all sorts of spurious signals to
appear. In the right place they can also cause strange audio
response.
Tom is doing a tremendous service to the boatanchor
community. I recommend him without reservation.

From: Jim Shorney
Topic: 18439 Message: 18529

The meter was a 50 uA taut-band movement, so a shunt resistance was needed to calibrate it. I have one in a WV-4 that came to me with a bad movement. The movement itself is an exact mechanical match from the same Jewell line. The casing was, IIRC, a four-hole mount vs. three hole, so I had to swap the case (and the scale, of course). It was easy to do. The only other differences are the pointer is black and the end of the pointer has a subtly different shape - not anything that a casual observer would ever notice; and the front cover had a grey lower portion instead of black. I used the front cover from the bad Drake meter, it fit exactly. I used a small trimpot in parallel and calibrated it against a known accurate meter. It has been in continuous service on my APRS digi ever since.

I have no idea what rack it came from. I bought it from an eBay seller because it looked very close in the pictures, and got lucky. Subsequently, another subscriber on Drakelist bought several and was offereing them for resale as a "kit" of sorts to replace W/WV-4 meters. I have no idea if he is still around or has any left.

I don't remember how much I paid for it either, but it seems to me that the combined cost of the bad WV-4 and the eBay replacement meter ended up being less than what a working WV-4 typically sells for. I see a lot of Jewell meters on ePay right now, some of which look at least a little similar, but I don't know if any of them could be adapted. It's possible that any Jewell/Honeywell MS2T meter may have a sensitive enough coil that the extra internal parts to turn it into a higher range voltmeter/ammeter could be removed and it could be made to work. The only one I have direct experience with was the one from a Motorola rack.

Here's a link to the original discussion:

It only gets worse. I got this note from Ram today.

Kevin
Unfortunately after we looked at the dial it would cost way to much to do. We can get the Jewell MS2T 0-200 UADC but would have to use the dial you have. The price on the MS2T is $357.14 and 10 weeks to ship. Let me know What you would like to do.
Barb

I find that you can get a W-4 for about $50 (give or take) on EBay so that is what I am going to do. I have Jewell meters set up on E-Bay to notify me if one comes up but all that I see are for other uses. A good hawk eye and patience could probably net you a meter only. I successfully painted a pointer red one time but after all this am going to leave well enough alone at Black.

Read the entirety of your "can not be delivered" message and see just who/what is bouncing your email. It's very possible your IP is listed on whatever spam remover Mindspring uses. It's happened to all of us at one time or another. I couldn't get a message through ARRL's email reflector for the longest time. Had to cleanse my entire computer before the problem finally went away. Damn hackers.

I did a couple of weeks ago with no problem when I purchased a CD product from him.
Which, by the way, I find to be a very valuable aid in the repair and maintenance of the Drake radio. Many hours had to go into a product of this nature. I recommend it to everyone! (Unsolicited commercial) HiHi!

I am on Netcom, another Earthlink company like
Mindspring. Yesterday my internet including the web and
e-mail went out for about half an hour. It could have been
my machine. I rebooted and was able to connect again but had
some problems later. There may be something on the Earthlink
web site.

Someone has been very busy writing some interesting code. I use two different email servers and both were down for two or three days two weeks ago. Both servers had over 400,000 emails stuck in their spam filters; the servers were trying to digest them and ultimately shut down the servers. The admin's had to manually remove the email from the spam folders; the system started working after two days but the email system is still slow as of today. There was a new infiltration that turned a bunch of the customer's computers into email spam servers sending untold amount of traffic to the email system.

I'm sure it's another Chinese college class project.

The following text comes from the "Drake Mods" version 6 file:-

" o Transmitter Driver Alignment

Drake goes into considerable detail on use of a loading network to
align the 4 series transmitters. Don't bother. Just align carefully
for maximum transmitter output at a low drive level.

The reason for this network is to simulate the loading when the
units are used in transceive. The better method is to slave the
units with the covers off both the receiver and transmitter and
align. This is much faster and much safer than playing with the
loading network method. There is some serious voltage inside these
units. Align each individual unit and then align in transceive both
ways - active PTO in the receiver for the transmitter and con-
versely. When setting up in transceive, you really only need to
touch up the most rear trimmer bank in the receiver and the front
bank in the transmitter. It is not as much a pain as you would think
and once set, you're done almost for life.

The loading network method is a waste of time. Information relayed
to me from the Drake User group indicates that even Drake themselves
does not bother with the loading network any more."

Marco -

There is a reason to use the alignment load as specified. The transformers being aligned are 'overcoupled' to provide a
wider bandwidth.

WITH the alignment load, you can tune the 'other' side for a peak. Reversing the load allows you to tune the 'other'
coil for a peak. The result is 'two' peaks, slightly apart from each other, and the overcoupling pushes up the area
between them. The result is a broader bandwidth.

WITHOUT the load, you peak the two coils, each of which affects the tuning of the other and you end up with a narrower,
single peak, i.e., a narrower bandwidth.

You can see the effect with a spectrum analyzer, but all it means is that the PreSelector / RF TUNE controls are both
sharper tuning, and most users don't know the difference!! :-)

I have been changing the meter from a W4 Wattmeter into a MN-2000 meter. Because of this I have had both faces removed from the meters. Both are in good shape so I scanned them both and put the files in the file section. Hopefully someday someone might be desperate for a meter face and can print one off.

I disagree....

I felt the same way for some years, probably influenced by misinformation in the Drakemod 6. While it IS the
definitive document on the Drake gear of the era, it is NOT totally accurate.

The loading network used in alignment has nothing to do with the transceive alignment, other than causing both units to
have a wider 'resonant' area when transceiving on other than exact 'transceive'. This is often why when transceiving
BOTH the PreSelector and the RF TUNE peak separately in two different directions from the SEPARATE settings.

There is plenty of information in reliable references about 'overcoupling' and it's effects.

Again, most users never know the difference!

I DO agree on the alignment of the INJ circuits with the two units cabled together, that is definitely worthwhile...

18558. MN-2000

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-07 02:00:52 UTC
From: <kmx888@...>
Topic: 606 Message: 18558

I just installed a meter from the W4 Wattmeter into an MN-2000 by changing the meter face. My W4 came in the three bolt pattern with a red pointer so it could not have been easier. However......Prior to my surgury the tuner worked great and would tune my antenna right down to 1:1. Now however the best I can do is 3:1 or so depending upon the band. I substituted an old MFJ that I have and it worked great so I can eliminate the feed cable and antenna.

The only other thing that I touched was to remove and replace a ground strap from one variable cap to the other. Can't to it wrong. Before I rip into this to find whatever it was I caused to happen, does anyone have any ideas of dumb things they have done to cause this problem?
Best,
Kevin

Marco -

A little concerned about your statement, 'just get new tubes'..... 'New tubes' are not an option to alignment, in fact
new tubes are the primary reason FOR alignment. Alignment is there to compensate for component aging, AND for variations
in tubes!

From: Steve Wedge
Topic: 18549 Message: 18562

Absolutely.

Without changing tubes, alignments should only require minimal tweaking. One should be able to go for years without changing the alignment.

Sample size of 1, admittedly, but that R-4 I had last year was like brand new. It probably sat in an SK's closet for 45 years. I hardly had to touch any adjustments when I checked it.

Most rigs I've received that haven't been hacked are usually very close.

Tubes had more variation than our modern solid state components.

Just off the tip of my head.

But the new meter may require the swr sensor to be recalibrated.

Yeah, both 200 ua...

But..., anyway a thought

Are you checking with a external mete? To verify what you're seeing on the drake?

FWIW, Earthlink just had another long system outage.
Probably an hour. No e-mail or web services. They say they
are still having a problem with Yahoo accounts. No details.
There was a similar outage a couple of days ago. Mindspring
and Netcom are Earthlink brands along with a lot of others.

Yes I am using a known to be good independent SWR meter. I haven't even thought about checking the accuracy of the meter I put in. I am sure the problem is something within the tuner itself. It is such a simple and built like a tank unit that I am puzzled. I guess I just need to take it apart again and see what I missed. My guess is that it must be something obvious.

First, put a separate SWR bridge in line right before the tuner
and see if that 3:1 is real.

I think I know where this question came from. I saw some C-Line sets on eBay where the seller was claiming it has this.

Perhaps he has some of those plastic dustcovers that have been on the aftermarket forever.

I just purchased a new inj cable and intend to do a proper alignment but am a little confused by a recent post about it.

I understand cabling both units together during alignment. But do I peak each unit separately and stop there or then re-peak them again in transceive with xmtr controlling and then receiver controlling? Thanks for any advice. Bob, NZ5A

You *** could *** peak everything when they're connected together. But, if the alignment's properly done, you really shouldn't have enough of a discrepancy to make that necessary.

You will not get the lock of the carrier oscillator that's available with the T-4XC, using the R-4B. Treat the transmitter as if it's a B-Line and adjust C61 on the receiver to be on-frequency with the T-4XC.

FWIW, Collins uses the same method for aligning the IF transformers in the 51J series receivers. These are slightly overcoupled to improve the skirt selectivity and produce a relatively flat-topped pass-band. They will not tune quite right if just peaked. I wish RCA had done this for the AR-88 which has two stages of overcoupled IF each with four transformers. Its possible to align it without a sweeper but is tedious. If not loaded while adjusting the two sides of an overcoupled transformer interact so the peak moves around.
The problem with overcoupled transformers is that the

resonance splits up into two peaks. Depending on how the mutual coupling is produced the peaks may be symmetrical about the center frequency or may have one at the resonance of the basic transformer and a second displaced in one direction. Pure mutual inductance will produce a symmetrical shape. By using a combination of overcoupled and critically coupled stages a relatively flat topped pass band with significantly steeper skirts is produced than one would get from the same number of critically coupled stages. The Super-Pro and SP-600 used this system but are easier to align because all the stages can be switched to critical coupling with a single peak. Some WW-2 military receivers had mechanical adjustment of coupling so that they could be aligned by simple peaking and then set for overcoupling.

73,

Steve Wedge, W1ES/4

FWIW, I use an R4B and T4XB and run them in transceive on WARC bands, 160 meters and to extend `10 meters. the system works very well. I have extra crystals in the receiver only because it takes quite a few more than the transmitter. It is a mild inconvenience not to have separate tuning but only that. The system used in the C versions is better but its possible to get the B line to be so close that you can't really tell. I may put additional crystals into the TX for 10 meters because the segment most used, at least locally, is not the segment covered by the factory crystal. Meanwhile the transceive function covers it fine.

I'm not asking about locking frequencies or getting them close---or am I?

My question, I thought, was about tweaking the injection trimmers for max out as per the manual. Gary suggested that both units be cabled together when you peak the trimmers. I did that and peaked each unit separately. Worked fine.

Then a recent post seemed to suggest that you repeal for max out in transceiver mode.

Do I need to do the re-peak in transceive mode too? That's what I was trying to ask. Maybe it didn't come out right.

I had an R-4C and t-4XC before; I understand only those two models locked together in terms of frequency.

Hopefully this clarifies things a little.

Bob

You *** could *** peak everything when they're connected together. But, if the alignment's properly done, you really shouldn't have enough of a discrepancy to make that necessary.

You will not get the lock of the carrier oscillator that's available with the T-4XC, using the R-4B. Treat the transmitter as if it's a B-Line and adjust C61 on the receiver to be on-frequency with the T-4XC.

From: Rich Arland
Topic: 18580 Message: 18580

Hey, gang....

KL0SW gave me a 2B carcass last year at Dayton, in the event I needed some parts for my 2B restoration. I have my 2B perking along just fine so now I need to find a good home for this carcass. There is no meter, the dial string and pointer are intact. No tubes. But someone might need some of the cans, etc, off this old warhorse. So if you need it, drop me a line OFF LIST and we'll get this on its way. OBTW: shipping will be up to the lucky recipient.

Hello Group,
I am in the process of aligning the Noise Blanker of my TR7; I have the extenders and all the tools. The problem is that the copy of the service manual that I have has low quality images, and I cannot locate with confidence the position of the "test point" on the board... it seems to be one end of C821, but if someone can confirm that, I would feel more confident :-)
Thanks for your support !

Hi Michele,
there are two versions. Which one do you have? Version 2 has a coax on
the component side which version 1 does not have.

From: Steve Wedge
Topic: 18598 Message: 18598

Just how effective is the pre-C-Line noise blanker supposed to be?

My R-4B is on 10 right now and there's what I would describe as some sort of motor- or arcing-generated noise that my NB is completely useless against. Signal level is about S3.

Steve,
I get a similar noise, that I cannot eliminate, whenever my iPhone or iPad is plugged into the charger, near the radio equipment. Mine is more of a whining sound. Get it on the R4B, R4C, 75S3C, and on my Kenwood. Oddly enough, the Hammarlund HQ 150, nor the A-Line (A1 & A4) receivers, get the noise.
Not sure what yours sounds like, or what may be causing it, but once I figured out the source, I simply put my iOS devices in another room to charge, when I want to get on the air.

Just how effective is the pre-C-Line noise blanker supposed
to be?

My R-4B is on 10 right now and there's what I would describe
as some sort of motor- or arcing-generated noise that my NB
is completely useless against. Signal level is about S3.

73,

Steve Wedge, W1ES/4

I have also been curious about this. The NB in my R4B
never seems to do much. I tested it in a couple of ways, by
means of the method suggested by Garey and also by setting
up a spark generator using a bug and choke, also by means of
a Tektronix pulse generator. With strong pulses from the bug
and choke or pulse generator I can hear and see on the
S-meter that it has some effect but on normal line noise it
seems to make no difference. I suspect that on ignition
noise it would probably work quite well but with modern cars
I never hear ignition noise. I've checked all the tuning
and circuits and can't find anything wrong with the NB, I
think its working the way its supposed to. Using the pulse
generator to mimic ignition noise it does make some
otherwise unreadable weak signals clearer. I understand
other versions of this type of noise blanker are no more
effective. However, the NB in my Kenwood TS-520S and in an
all solid state Kenwood (can't remember the model number) in
the ham club shack at work _will_ reduce line noise
considerably and prevent it from desensitizing the receiver.
FWIW, none of the conventional noise limiters on any
boatanchor I have works at all on CW. The adjustable one on
my AR-88 does limit but doesn't really do anything useful.
In the others the "carrier" from the BFO makes them useless.

18602. TR7A sensitivity

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-13 17:43:45 UTC
From: <f6dfz@...>
Topic: 18602 Message: 18602

Hi to the group,

This afternoon, I measured the sensitivity of my TR7A.
Rig is unmodified as long as receiver is concerned. 300 Hz CW filter in line.
80 m : MDS = -134 dBm
10 m : MDS = -136 dBm.
When I read that the TR7 is deaf and needs a RF preamplifier, it's very funny.

Georges

18604. Re: [DrakeRadio] R-4B NB

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-13 18:36:46 UTC
From: Garey Barrell
Topic: 18598 Message: 18604

Steve -

The noise blanker circuit topology is the same from the R-4 through the TR-7.

It was initially designed to remove ignition noise from the TR-4, which was designed for mobile SSB..... At the time,
cars produced a pretty steady stream of pulses that were very narrow and very high. The blanker essentially 'punched a
hole' in the signal path, turning off the receiver for the duration of the pulse. It did that very well. The waveform
on the front cover of the R-4B shows the process graphically.....

Resistive ignition cables came into general use, primarily thanks to all the other electronics in cars, and a new
scourge appeared. The Russian 'Woodpecker' over the horizon radar had a similar characteristic, except the pulses were
slower, and a bit wider. Time constants were adjusted in the C-Line blanker to allow it to deal with those a little
better. The catch is that the wider pulses required bigger holes, and there is a point of diminishing returns where you
have more 'hole' than 'signal', and yes the noise is gone but there isn't enough signal left to be intelligible.

Narrow pulses, whether generated by auto ignition systems, an antenna lead dragged across the chassis, or some sort of
pulse generation system, can drive the S-Meter to 10 over 9+ and obliterate fairly good signals. Turning on the blanker
will drop the S-Meter down to the signal level and make it perfectly readable. Obviously the object is to prevent the
noise pulse from reaching the AVC amplifier, shutting the receiver down for the release time of the AVC.

Bottom line, all the noise blankers do a good job of taking out ignition noise, electric fence noise, distant lightning
and any other noise consisting of short duration spikes. The wider the spike, the poorer the reduction. Buzzing,
whining, grumbling and other assorted 'noises' are NOT blankable as the 'average' level is too high, i.e., the radio
isn't ON long enough for the signal to be intelligible.

From: Fernando
Topic: 18606 Message: 18606

Hello.

How is the Passband Seletor Lever removed?

Does the whole shaft comes out the front

or is the lever pressed fit onto that shaft?

I’m trying to remove the front panel of this R4.

Thanks for any tips.

Fernando N2FQ/6

The entire shaft come out. It 'breaks' at the copper tube just in front of the Passband Tuner. Be careful to not
stress the PB Tuner switch wafer.

I put a hand on either side of the copper tube, and press my thumbs together for controlled pressure with no surprises.

There is a flat piece of spring steel inside the copper tube that may fall out when you remove it. Don't LOSE it!! It
provides the 'flat' for the shaft inside the tube.

From: Steve Wedge
Topic: 18598 Message: 18608

That's pretty much as I reckoned, Garey. I guess what I'll take away is that the noise spike have to be fairly high-amplitude before the NB will take them out. Yes, I knew about the covers on the manuals. I'm also old enough to remember many cars around still with non-resistive ignition wires. Especially the motorheads who ran solid copper cables. I can see lots of use for the NB's in the TR-3/TR-4, but not so much with the Twins.

Yeah, I turned on one of my R-4's and A/B'ed it with the R-4B and the NB was doing about the same, which is to say nothing on the noise that was present at the time.

It's interesting to note how much the NB's for the C-Line and TR-4's go for, given that their usefulness isn't quite that high nowadays. It's more a collector value sort of thing.

Oh, well. Back to my painting...

Subject: Re: [DrakeRadio] R-4B NB

Steve -

The noise blanker circuit topology is the same from the R-4 through the TR-7.

It was initially designed to remove ignition noise from the TR-4, which was designed for mobile SSB..... At the time,
cars produced a pretty steady stream of pulses that were very narrow and very high. The blanker essentially 'punched a
hole' in the signal path, turning off the receiver for the duration of the pulse. It did that very well. The waveform
on the front cover of the R-4B shows the process graphically.....

Resistive ignition cables came into general use, primarily thanks to all the other electronics in cars, and a new
scourge appeared. The Russian 'Woodpecker' over the horizon radar had a similar characteristic, except the pulses were
slower, and a bit wider. Time constants were adjusted in the C-Line blanker to allow it to deal with those a little
better. The catch is that the wider pulses required bigger holes, and there is a point of diminishing returns where you
have more 'hole' than 'signal', and yes the noise is gone but there isn't enough signal left to be intelligible.

Narrow pulses, whether generated by auto ignition systems, an antenna lead dragged across the chassis, or some sort of
pulse generation system, can drive the S-Meter to 10 over 9+ and obliterate fairly good signals. Turning on the blanker
will drop the S-Meter down to the signal level and make it perfectly readable. Obviously the object is to prevent the
noise pulse from reaching the AVC amplifier, shutting the receiver down for the release time of the AVC.

Bottom line, all the noise blankers do a good job of taking out ignition noise, electric fence noise, distant lightning
and any other noise consisting of short duration spikes. The wider the spike, the poorer the reduction. Buzzing,
whining, grumbling and other assorted 'noises' are NOT blankable as the 'average' level is too high, i.e., the radio
isn't ON long enough for the signal to be intelligible.

Doug -

Oh yes, I meant to mention that before. Electric fence noise can be a real pain, and the NB does a great job on them.

There's actually still quite a bit of noise generation that IS affected by the blankers. It just has to have a low
AVERAGE power portrait.

They're still valuable because they can be the difference between a QSO or not.

This I have said. However, I have also noted that in the R-7 the preamp can sometimes make very weak signals easier to copy. But it does not improve sensitivity.

Topic: 18602 Message: 18620

Hi Jim,

I also had a R7 in the past. Terrific couple for its time, with true double reception.
I prefered the audio of the TR7, but difficult to really tell if it's a generality.
I rarely used the preamplifier, it brought too much noise for my taste.
I make a remark similar to yours about the 300 Hz CW filter. When you switch it in, the receiver seems deaf. But the signal to noise ratio is of course better than those of the 500 Hz filter ; you just have to augment the AF gain to compensate for the slight loss of audio.

Georges

My TR-7 not A is hotter than my Icom IC-7200. It measures every bit of -130 or better on all bands. Amazing for its vintage.

Need to sell my Drake HF Station. In great condition. I have no Ham Shack anymore. Tested the other day at a friends house and everything seems to still work. The pots are dirty and need cleaned. Probably needs a good dusting inside as well. The caps in the power supply are nice and no signs of leaking. Feel free to ask me any questions and I do have many pictures. I will take the highest offer that I receive. It will be sold as is, only due to age. Shipping will be from 84321.

Kevin -

We much prefer that you state a price when you put something up for sale on the list. It's not a _rule_ as sometimes
you have items that are difficult to price. But what you are offering is pretty easy to estimate value. Someone could
always offer less, or more, if they wish.

We are NOT an auction site, so please include a price on any offers for sale.

From: <f6dfz@...>
Topic: 18602 Message: 18624

This is not the end of TR7 qualities. For example, check Image Rejection ; the TR7/TR7A is well over 100 dB when "high end" rigs like TS990, FT5K, FT3K are near 65 dB.
Check also IF rejection, IMD2...
The TR7A has general coverage, when down conversion design have a gap near the IF.
Try to service these new rigs or even to fully understand their schematic diagrams. Did you see any microprocessor inside your TR7 ?
The TR7 and similar up conversion rigs were the answer to the problems due to down conversion designs.
It's a pity to see them back. Good gain distribution is the answer to very high closed spaced signals IMD3 (see the Hilberling up conversion design and its 50 kHz wide roofing filter).
Down conversion designs with narrow roofing filters are a poor answer and reintroduce problems solved 35 years ago by Drake and others.
If the ranking in Rob Sherwood's comparison table was based on an other criterion than 2 kHz IMD3, all rigs would be up conversion, or now direct sampling, but certainly not down conversion.

Georges

18625. FS: 2 x SPR-4's

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-14 19:21:25 UTC
From: VE3AX/7
Topic: 18625 Message: 18625

I have two SPR-4’s available for new owners as follows;

Both have standard xtal sets and no options. They are mid-run units with glass epoxy PC boards and the option to change the fixed AGC time constants.

#2722
Replaced bad B-5030 transistor in the AC power supply.
Replaced the front panel with a very good one from #2737. In the right light you can see where someone had a sticky label applied near the meter so it has faded differently from the rest of the panel.
New blue/white dial & meter filters from WA9TGT.
Repaired broken PTO shaft.
Cleaned all PTO gears & dials and cleaned/re-lubed bearings. Dial is not quite as smooth as #2737 below.
New chassis rubber bumper from KC9IEQ.
New rubber bumpers on feet.
Re-painted white lines on knobs.
Installed new foam strips between front panel and sub-panel.
Touched up paint chips on edges of cabinet. Cabinet has some slight surface scratches.
Installed a permanent AC line cord – no extra holes drilled and is entirely reversible – original connector & hardware will be shipped with radio.

Asking $325 + shipping.

#2737
Replaced two bad B-5030 transistors on the audio board.
Replaced the front panel with KF8MW replacement (C-line style with no brushed aluminum edge).
New blue/white dial & meter filters from WA9TGT.
Replaced bad tantalum cap in PTO.
Cleaned all PTO gears & dials and cleaned/re-lubed bearings.
New chassis rubber bumper from KC9IEQ.
New rubber bumpers on feet.
Installed new dial window from WA9TGT.
Machined and installed/lubed a new Preselector shaft as the vernier was originally stuck solid, then when freed up, it had insufficient friction to drive it due to the worn shaft. Nice, smooth, positive operation now.
Re-painted white lines on knobs.
Installed new foam strips between front panel and sub-panel.
Installed a permanent AC line cord – no extra holes drilled and is entirely reversible – original connector & hardware will be shipped with radio.

Cabinet on this one has a faded top and is awaiting an overspray with Krylon. Otherwise in good shape. Does have a very few light scratches.

Asking $375 + shipping.

Please reply off list to ve3ax@.... Pics available.

73 and thanks

Peter

I also preferred the TR-7 audio at first. Even so, after I learned that K9JU had found that there is a fair amount of IMD in the audio stage, so I had done some audiophile-style component changes to try to improve performance. Results were good, so I took it a step farther with the R-7 and extended the frequency response as well. Now I prefer the R-7 audio, and I need to go back and work on the TR-7 again! Signals seem to "stand out" better and are more intelligible.

Working split with that pair is lots of fun! It helped me to bust a 30 KHz wide RTTY pileup and snag FT5ZM earlier this month.

Georges,

I will need to go back and organize my notes to provide exact info. Part of what I have done is based on the work of those two fine hams that you mention. Audiophile improvements that some will no doubt snicker at include replacing 2N3904 transistors with BC549B, metal film resistors in place of carbon, ceramic coupling capacitors in the audio path replaced with poly, and increasing the value of some decoupling capacitors. Frequency response extension involves changing the values of selected parts as described by the others. The theory there is not to produce a "hi-fi" radio per se, but to improve articulation and reduce distortions caused by phase shift at the edges of the audio passband. I have no measurements to prove definitively that this is so, but it sounds good on paper... :)

K9JU found the IMD to be quite objectionable to his ears, and went to greater lengths than I did. He has not published his work anywhere that I know of at this point.

A couple of things from an old audio person: There is
probably no advantage in changing from ceramic to plastic
film caps. Very high K ceramics, Class-2, have some voltage
```

coefficient of capacitance but in most audio applications such as coupling capacitors there is a DC voltage on the cap which is quite a bit higher than the AC voltage so the effect of the capacitance variation is minimal. Capacitors do not cause harmonic distortion. The voltage variation could, in principal, cause intermodulation distortion if only AC is present.
Carbon composition resistor also have a voltage coefficient of resistance. Here again the amount depends on the ratio of DC to AC on the resistor. Either carbon or metal film resistors have virtually no voltage variation. It was found long ago that film resistors can make a detectably difference in feedback networks.
My experience is that clean audio in a communications receiver definitely does make a difference, even with CW, because the distortion, both IM and harmonic, exaggerates the effect of noise and QRM.
IM is best measured with a spectrum analyzer but can also be measured with a selective voltmeter. There were standardized methods of measuring IM using two frequencies but both of the methods commonly used in motion picture optical recording could miss problems so its a good idea to measure using several combinations of frequencies. The two general methods are: 1, to use two widely spaced frequencies, one near each end of the audio band limit and look for modulation of the high frequency by the low frequency, and, 2, to use two closely spaced frequencies of equal amplitude. The second method can be used on narrow bandwidth channels and is the desirable one for distortion measurements of SSB amplifiers. Harmonic distortion measurements are not suitable for narrow band systems since the frequency limitations will eliminate the harmonics.
IMO IMD is very audible. The two kinds of distortion come from slightly different mechanisms in the amplifier so one must measure both.
Another opinion: Simple and not very good audio amplifiers are very common in communications receivers, I think because the assumption was made that the quality didn't matter because of the limited bandwidth and limited dynamic range of the signal. This is, again IMO, a mistake. Of course, simple amplifiers are also cheap. "Good enough" often isn't.

Nope, it's not just you. I thought the same thing. I enjoy this group more than most because of its polite nature and appreciation for Garey's contributions to us all. My hope is that the seller receives exactly zero responses from the list.

18639. Re: [DrakeRadio] For Sale: Drake TR-4C, MS-4, AC-4, MN-4

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-15 20:00:19 UTC
From: Dan Galligan
Topic: 18622 Message: 18639

While I agree with the sentiments expressed here, to be the contrarian, and point out what is likely the obvious. If he leaves it open on price, and doesn't know the value, it does give the enterprising capitalist, the opportunity to low-ball him, and be in a position to profit from the seller's ignorance.
Still, the courteous thing to do, is to have an asking price. The folks here, know their value, and would certainly enlighten the seller, should his asking price be out of line, high, or low.

There is much historical data reference the price. At his asking price, he is not likely to sell it. But with his tone, he will be stuck with it.

18641. Re: [DrakeRadio] AC3 and 240 volt AC mains

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-16 00:57:55 UTC
From: Steve VK2SJA
Topic: 18076 Message: 18641

Hi Garey/All,

Alright I must have been careful enough. I'm still here and no Yucko-Shocko!

With the assistance of one of my Elmer's, Ian, VK2IAN (who does know what he is doing and is a licensed to play with mains voltages) I have now adapted the AC3 power supply with an input auto-transformer that drops the 250vac mains at this QTH down to 221vac. We also threw in a soft-start module for good measure.

Now the transformer when it runs unloaded produces a nice soft "I'm alive hum" and does not sound like it is going into saturation.

But I'm still worried because now some of my voltages look suspiciously low.

Here is what I have *unloaded*:-

+650vdc rail => +631vdc
+250vdc rail => +261vdc
BIAS => -43.7 to -86.4vdc
Filament Heater => 12.3vac

So my question is:-

"Is the radio (TR-4C) going to be happy with these levels?"

73, Steve.

Date: 2014-02-16 02:04:01 UTC
From: Bill Jackson
Topic: 18643 Message: 18643

I have a later model Drake R-4C where the S-meter won't stay zeroed. It wanders around, plus or minus a couple of S-units over a period of hours. It is not the potentiometer, as the zero adjustment is very smooth, it simply won't stay adjusted.

The receiver otherwise works fine and I cannot relate the problem to any outside cause, such as room temperature or varying line voltage. Any ideas on where to start looking?

Thanks in advance.

Bill, K9RZ

Afternoon Gentlemen,

TR-4C restoration.

Currently checking (and replacing) screen grid resistors 68ohm R42, 43 and 44.

Question. Do I care about R176, 177 and 178, also 68 ohm?

I have enough metal oxide 2 watt 68 ohm 5% to do all. Same size as ones coming out. Metal oxide suitable here?

Thanks!

73, Steve.

18651. Re: [DrakeRadio] AC3 and 240 volt AC mains

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-16 05:04:48 UTC
From: Garey Barrell
Topic: 18076 Message: 18651

Steve -

The HV is low. Gives me concern about the condition of the electrolytic filter caps. IF they are original, they're
probably leaky and are dragging down the voltage. If that IS the problem, they will overheat, and could even 'explode'
by blowing out their vents (provided for just such a contingency. If in fact they are original, you may want to get the
ESAC-3 (?) rebuild kits from Harbach.com.

I don't know if you have my CD or not, but there is a lot of information on the AC-3/4 in the MISC directory. With a
121 VAC primary voltage, the Red leads on the power transformer should measure around 265 VAC, the Yellow 108 VAC, the
Blue 98 VAC and the Green 14 VAC. The unloaded DC voltages should be considerably higher than what you are measuring.
740, 300, -100 VDC NO LOAD.

To answer your question, yes, the TR-4 should run ok at those voltage, but less than optimum, and won't make full output.

Hi Garey,

Thanks for the reply.

Power supply has already been reconditioned with AS4AC-3. The auto-transformer is constructed from a 4A multi-tap secondary. So I can re-tap to raise the output. I'll try raising the secondary back up to say 230vac and see what happens. I just remember the onset of what I associate with harsh saturation sound happened pretty quickly after 220vac. See if I can't hit a happy medium.

Of course this rig has output to burn with three tubes. And so if all that happens is slightly reduced output I'm not particularly worried. So long as the rest of the circuit hums along happily?

Yes, I most certainly do have your most excellent Service CD-ROM. Would not be attempting this without!!

I'll go and have a look-see at the AC-3 info.

73, Steve.

18654. TR-4C meter shunt resistors?

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-16 07:38:41 UTC
From: Steve VK2SJA
Topic: 18654 Message: 18654

Hi All,

After advice and guidance regarding TR-4C meter shunt resistors. Values and adjustment procedure.

I checked R45? (doing this from memory) on the relay PCB measured 2 ohms spot on.

Is it R13 or R13A that makes up the other part of this story (or both)?

R13A is the one mounted on the plate control shaft slider switch and factory selected.

So what s the correct procedure here to make sure the meter is reading correctly?

73, Steve

Steve,

My friend WA5VGO just went through changing the TEST resistor on the switch around a week ago. First off, he told me he found the meter was not linear and will not be totally accurate everywhere on the scale. So he decided to make it accurate at 400ma, I believe. He temporarily installed a VOM in line or in series with the power supply feeding the finals. He then tuned the transceiver up to 400 ma based on his VOM and then test selected a resistor on the slide switch to show the same 400 ma reading. What I can't tell you right now is where he installed the VOM in line with the power supply feeding the tubes. His thought was to make the meter pretty accurate around where he most likely would be drawing current during normal operating of the rig during tune up. (His resistor was originally not giving an accurate reading at 400 ma and as I said, he found the meter on the Drake was not accurate at other current levels. He did this to three of his TR-4s and he said each one needed a different resistor and the linearity of the three meters were not the same. That is a meter was more linear on one radio then on one of the other radios.)

Lee, w0vt

Hi All,

After advice and guidance regarding TR-4C meter shunt resistors. Values
and adjustment procedure.

I checked R45? (doing this from memory) on the relay PCB measured 2 ohms
spot on.

Is it R13 or R13A that makes up the other part of this story (or both)?

R13A is the one mounted on the plate control shaft slider switch and
factory selected.

So what s the correct procedure here to make sure the meter is reading
correctly?

Topic: 18643 Message: 18656

I agree.

If the S meter changes as the RF gain is rotated CCW and CW, i.e., meter rises above and falls back towards zero, then the operating bias applied to the grid of the tubes through the RF gain control is working. By rotating the RF gain control CCW or CW, the operating bias to the tubes is changed, made more negative in a CCW rotation and made less negative rotating in a CW rotation. The S meter will respond to the grid voltage changes to these stages, i.e., the S meter rise above zero (CCW rotation) or fall back towards zero (CW rotation). This test and the following VTVM grid voltage test/measurement is performed with the antenna disconnected.

Set the RF gain control fully CW then connect a VTVM to pin 1 of each tube, V5, then V1 and V3. The operating grid voltage should be negative. As the tubes warm up a gassy tube's grid voltage will become less negative and could even change to a positive voltage. The offending gassy tube's grid voltage will be much more negative or become positive then the other tubes.

I had this type of problem with my Heathkit SB-100, the first IF amp, a 6AU6, was very gassy which caused its grid voltage to be initially a negative 1.5VDC from a cold power on. However, during the first minute, the gird voltage would become less and less negative and finally settle, after 2 minutes, at +1.7VDC. The gassy first IF amp caused the second IF amp's grid voltage to change positive as well but at a less positive level. +.8vdc. The gassy first IF amp also affected the receiver's RF amp and first mixer making their grid voltage less negative but not positive.

Steve -

Yes, R13A on 'my' schematic is the 'select at test' resistor and is there to compensate for R45 tolerance and meter
characteristics. The meters are NOT precision devices, I think Drake paid less than $1 for them in production
quantities. The R13A was mine, because there were TWO R13s on the schematic! :-)

The most important reading for the PLATE meter is the BIAS measurement, so that is where you need to calibrate it. The
much higher 'loaded' current is of no real importance, there you're only looking for a peak or null. So. Assuming you
have a decent DMM, easiest is to measure the value of the shunt resistor (R45) as close as you can, then measure the
voltage drop across it as accurately as you can. Then e.g., adjust the BIAS for 0.20 VDC across R45 and select a
resistor for R13A until the meter reads 100 mA. I use a small pot, and adjust it for exactly 0.20 VDC. It's good to
approach 0.20 VDC from higher and lower to see how the meter responds. Then measure the resistance of the pot and
install the closest 5% (or 1% if you have them) resistor.

If you don't have a DMM, you can just ground the 'bottom' end of R45 through a mA meter and set for 100 mA.

This gives you what you need to set and/or keep an eye on the BIAS current, the rest of the scale is unimportant.

Subject: [DrakeRadio] TR-4C screen grid resistors?

Afternoon Gentlemen,

TR-4C restoration.

Currently checking (and replacing) screen grid resistors 68ohm R42, 43 and 44.

Question. Do I care about R176, 177 and 178, also 68 ohm?

I have enough metal oxide 2 watt 68 ohm 5% to do all. Same size as ones coming out. Metal oxide suitable here?

Thanks!

73, Steve.

Group,

It was not my intent to be rude. I was just asking if it made him happy. I just wanted to know if my post was better. People mistook a simple question as being rude. I am not sure of what it is really worth. That is why I left it up for offers. So I looked and came up with a number. Is it too high? Is it too low? I don't know. I hoped that make an offer would give me some ideas. I am sorry if my posts sounded negative. I thought I would post here, to give people who actually appreciate these radios a chance to own one. Again, sorry if it sounded negative.

OK. All I ask is a 'target' price. There are several sources of pricing info around, including eBay (about +20% over
market), WB4HFN, etc. Nothing wrong with posting a price you think is high, you'll get either offers of less, or
questions of your sanity, or 'nothing'. You can then decide to accept a lower offer, reduce the price, or put it up for
auction on one of the sites.

It's also good to offer a statement of general condition, as that can have considerable effect on what someone is
willing to pay. Based on WB4HFN prices, $600 is a reasonable starting point for equipment in average to better condition.

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

Thanks for your comments, Richard. I have some interesting 3d spectrograms from Wavelab LE that show something is happening (or, less of something is happening) between the before and after samples. I wouldn't expect my methodology to pass critical muster, but I set up a crude "simulated" 2-tone test with my HP 8656 signal generator. We work with the tools we have. The bottom line is that the R-7 is easier to listen to now, as was the TR-7 after the first round of changes. The fact that I go to the R-7 receiver first now was somewhat surprising to me. But shouldn't it be that way? Arguably the R-7 should be a "better" receiver than the TR-7.

All "audiophool" kidding aside, these component changes at least won't hurt anything (except perhaps the "collector's value" of the radio, which I don't care so much about). And if they help, that's great. K9JU is a CW operator, and his comments were that the weaker CW signals were modulated by the noise in the TR-7. The problem seemed centered around the audio preamp Q1113, but the only cure he found for it was to make it an emitter follower. He had to add extra "stuff" to overcome the loss of voltage gain, which I wanted to avoid. He did a lot of work on this, and seems quite happy with the results.

I'm curious, so I must ask. I don't regularly check eBay, to see if there have been any sold, but I have always wanted one radio, over and above all others. But, I am not sure if it ever was a realistic dream, or more akin to wanting to locate buried treasure.
Has anyone on the list ever owned, or operated, a TR-77? I've seen photos, but, all of them were seemingly Drake promotional photos. I have never known anyone who actually had hands on one.
Now, the $64,000.00 question is.....IF they ever were produced, and marketed, does anyone know how much they ought to fetch? I'm guessing that they make hen's teeth appear to be common, and slightly more scarce, than Bigfoot. Therefore, I would certainly expect them to make the Gold Dust Twins, appear to be a real bargain. Am I in the right ballpark, or is it more common than I think?

If I remember correctly there was a guy in the UK who was selling one a few years back. It was posted on another Drake centered list. Again, if my memory was correct, he wanted around 3,000 for it, but I don't remember if that was dollars or pounds. To be honest, it was the only time before your email that I ever heard of one.

Geoff.

Dan:

I can’t answer if there ever was a real TR-77 - Sindre would be able to answer that one, but I can say the later production model TR-4310 is real. I have one paired with a “homebrew” R-4245 (R-4245 panel on an RR-3) and an MN-4438 tuner. Makes a really nice 100 w station with RV-75-like stability. It is not as convenient to use as a ham rig though, as the start-up frequencies for the band segments are outside the ham bands. I’m just partial to the Drake commercial rack mount gear.

The knobs are different on the TR-4310 versus that shown in the TR-77 literature. Not sure if there were other differences.

Other really rare items in that line up include the L-77 Amp and the MN-4439 high power tuner. There are probably a few of those floating around France/Italy from an old Monaco commercial station. Sindre managed to get hold of one of the L-77’s but never heard if he managed to find a 4439 yet.

There were about 20 TR-4310’s brought into Canada when Fred Hammond (SK) of Hammond Manufacturing got a deal on some of the last ones made and lined up a bunch for his friends. I picked up mine from one of those friends of Fred’s many years ago. Price was not outrageous, but not cheap either – not as bad as a late TR-7A /RV-75 these days! Most of them were sold off, many to Europeans who paid pretty big dollars for them. I only know of one other TR-4310 remaining in Canada, but of course there could be others I am not aware of.

Yes it works. I had to install a tube mic pre-amp in line to provide sufficient drive to the radios TR-4 and T-4XC. I've used several Heil mics on the drakes and they just don't drive the rigs at all. Otherwise you have to be within an inch if the microphone. If you're referring to the XLR connector pin 1 and 2 are the mic, I believe pin 2 is mic positive white and pin 1 is mic negative black. Look at Heil's website and the have a mic wiring guide. Black and shield go to the ground on the plug that goes to the rig and white goes to the ring. Pin 3 and 4 are PTT. ONE needs to go to the tip and be grounded when PTT IS pushed. Double check pin out as I don't have it in front of me.

Jim,

You are absolutely correct however; I wanted to boom mount my Heil Classic so that I did not have to hold the heavy base while I talk. I set the boom such that my face was around 3" to 4" away from the mic; this allows me to have easier access to my computer screen, watch meters and keep an overall eye on the operating station. I found that at this distance the mic fell on its face. At the suggestion of my Elmer, I bought a $40 Behringer Tube mic preamp; I add just a smidge of preamp gain and all is solved. I monitor for over drive and background noise and everything seems to work quite well.

I'm 6'5" and no matter how I configure a desk mic, it's no where near my face; the desk is too short and so is the mic stand. I therefore end up holding the 10 pound base. After about 30 minutes or so, I get tired of holding it. The boom works out great for this but the stock Heil Classic doesn't have anywhere enough drive for the radio. On the other hand, my UN amplified D104 mics will overdrive the rigs at a 3" distance.

This is why I am doing what I am. Maybe someone has a better solution or has more info to add however; this is my experience.

Hi Steve,

No signs of stress. But definitely outside 5% tolerance.

So was R176, out of tolerance that is, when I pulled one end and checked it out of circuit (tubes still installed - not sure of effect on measurements).

As I try and use the Yahoo search facility to learn from the past I can see lots of recommendations to replace the "screen grid resistors" which if my understanding is correct are the R42, 43 and 44. Which all come from the same tag strip point, one for each tube. But I don't see in the archives regular discussion about replacing R176, 177 and 178. So I'm guessing that these are somewhat non-critical in value?

From the schematic it doesn't look like any of these are critical enough to require precision resistors. 42, 43, 44, are screen bypass resistors, I am not quite sure what 176, 177, and 178 are supposed to do. They are connected across the two screen pins of the tube so are across essentially a short circuit but may be parasitic suppressers. All were rated at 10% originally. They can probably be pretty far off this without having any serious effect. New resistors are typically 5% and can be used if there is any doubt. It is very common for carbon composition resistors to rise in value with time and heat although the amount varies a lot with brand and value. It is high value resistors, say 1/2 meg and above which are often very far off and should be changed. My experience with Drake is that they used a couple

of brands of resistors, the ones with smooth surfaces seem
to be pretty stable, the ones with longitudinal mold marks
are no at all stable.
I think the cathode resistors should be pretty close
since they are part of the circuit that measures total
current. Modern metal oxide resistors are usually 5% and
will last forever.

I tend to agree that screen resistors are less critical. However, if I measured any and they were out of tolerance, I'd change them.

Since we seek matched PA tubes to keep one from doing substantially more work than the other[s] we do need to keep an eye on the cathode resistors and the plate parasitic suppressors - but especially the cathode resistors. They're only 15 ohms and are in series with the flow of plate current. It isn't as much if they're 15, or 18 or 13 ohms, than that they all be the same value within a couple percent. If you have one that's 15 and the other is 18 ohms, they're different by 20% based on the 15 ohm resistor's value. Either that, or, if you have a set that's not quite matched, put the "hotter" tube in the 18 ohm resistor's socket.

I tend to agree that screen resistors are less critical.
However, if I measured any and they were out of tolerance,
I'd change them.

Since we seek matched PA tubes to keep one from doing
substantially more work than the other[s] we do need to keep
an eye on the cathode resistors and the plate parasitic
suppressors - but especially the cathode resistors. They're
only 15 ohms and are in series with the flow of plate
current. It isn't as much if they're 15, or 18 or 13 ohms,
than that they all be the same value within a couple
percent. If you have one that's 15 and the other is 18
ohms, they're different by 20% based on the 15 ohm
resistor's value. Either that, or, if you have a set that's
not quite matched, put the "hotter" tube in the 18 ohm
resistor's socket.

73,

Steve Wedge, W1ES/4

The cathode resistors in both my TR-4 and T4XB were of
the two types I mentioned. The smooth ones were very close,
the seamed ones were very far off, I think one was 30 ohms.
Anyway, I dumped them all. If you know the screen current
you can calculate the drop through the resistors. In any
case modern resistors are very cheap so there is no reason
to hang on to the old ones.
Remember that while many resistance measuring
instruments may not be too accurate for absolute value they
can still be used to match within very close tollerances.

Ahhhhh, but with that wonderful VRTO built right in!

Geoff:

I think there was an R-4245/TR-4310 set that came out of the the British Isles a few years ago on E-pay. Seems to me I saw a post somewhere where somebody commented how ridiculous it was someone would pay $3000 for a what was perceived as a rack mount TR-7 and R-7 combo. Hoo boy – I would have! Hence the reason I am using a fake 4245 with my 4310! It's not a bad compromise though and is fully reversible should the need arise. I have it tagged on the back as a fake along with the location of the original front panel and knobs in case I drop dead someday!

Checking Sindre's site today, I see he is still looking for an R-77 and MN-77 but there is no TR-77 listed there as a want, so maybe he did find one, although the many pics he has on his site do not show a TR-77 per the sales brochures, but there are certainly a few TR-4310/R-4245 combos there. I have hosted Sindre at my home when I was in Ontario and we had many a good chat about the "rare ones". At that time he did not have an L-77 amp but e-mailed me years later with pics of the one he managed to snag out of France, I believe – no doubt one of the 6 Monaco station amps. I have attempted to find one myself but to no avail. With retirement looming, I am trying to throttle back to the rigs I like the best instead of leaving a Drake museum for my wife to dispose of.

Hey Sindre...you reading all this????

Thank-you Richard, Garey, Steve and to all who replied.

All understood now. Confident that I can now calibrate meter and set BIAS correctly.

Rig is coming along nicely. Just hope that she wants to "fly" when we get to "Smoke-test II". Smoke-test 1 wasn't too successful. No smoke but no audio either and a 3A@110 AC volt fuse blew after a minute or so. Finals cage quite warm to touch. So the rig had gone into TX unexpectedly. Still not sure if this was a fault or operator error. Quite possibly the later.

18684. T-4X driver.

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-17 23:32:56 UTC
From: Steve Wedge
Topic: 18684 Message: 18684

I've got a T-4X that apparently ate its 12BY7 when the insulated line going through the RF deck to the neutralising cap C48/49 shorted to the chassis. It burned up R26, which I've replaced. T7 still has continuity. There's evidence of the 12BY7 overheating: discoloration of T6's can nearby from excessive heat. I replaced the 12BY7 and though the voltages look better, I'm still not convinced. About 250V on the plate, 190V on the screen and 7V on the cathode. Grids are at chassis potential.

What is that small cylindrical component coming from the plate (pin 7)? I always thought these were inductors but there's no continuity. Are they caps, as I suspect? This one is BRN-BLK-WHT-SIL from what I can see. I'm interpreting this as 10 with a 9 multiplier. Any input here?

Topic: 18684 Message: 18685

Hi, Steve:

The cylindrical object you see is most likely a capacitor. The ones I've seen are usually temp comp types but don't have to be. A chart in an old Allied Electronics Data Handbook suggests the color code will be a 1.0pf capacitor (Brn-Blk-Wht, Wht being a multiplier of 0.1) . The chart does not show the Sil band but I'd guess it might mean +/- 0.1pF (10%).

My T-4X manual shows a 1.5pF cap (C33) from the plate of the 12BY7 to C31, a 500pF "bypass" on the low end of the V3 output tuned circuits. The two caps are a fixed value neutralizing circuit similar to the tunable neutralizing used for the final amplifier. I haven't looked at my T-4X but a change in value may have occurred over the years. There is a chance the Blk band you see is a Grn that changed due to years of heat exposure.

Thanks, Bob. I always thought those were inductors, so I was surprised when I found out it wasn't.

Still trying to figure out what's not working in this one. I suspect if I put a scope on the grid that it will overload the circuit and I won't see anything. Will check it tomorrow.

Steve Wedge, W1ES/4

> The cylindrical object you see is most likely a capacitor. The ones I've seen are usually temp comp types but don't have to be. A chart in an old Allied Electronics Data Handbook suggests the color code will be a 1.0pf capacitor (Brn-Blk-Wht, Wht being a multiplier of 0.1) . The chart does not show the Sil band but I'd guess it might mean +/- 0.1pF (10%).
>
> My T-4X manual shows a 1.5pF cap (C33) from the plate of the 12BY7 to C31, a 500pF "bypass" on the low end of the V3 output tuned circuits. The two caps are a fixed value neutralizing circuit similar to the tunable neutralizing used for the final amplifier. I haven't looked at my T-4X but a change in value may have occurred over the years. There is a chance the Blk band you see is a Grn that changed due to years of heat exposure.

18687. When you can't set the bias to .1 ampere on a TR-4c, you...?

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-18 02:02:14 UTC
From: <resluder@...>
Topic: 18687 Message: 18687

Hello gang,

A silent reader from time-to-time, and long-time lover of most things R.L. Drake here. I decided to dive into a TR-4c that I took ownership of back in late 2012. I turned it on with the appropriate controls placed in the correct position, and attempted to set the bias. I couldn't get it to move no matter how much I turned the bias pot on theAC-4. It stayed at .05 ampere.

I suspect I need to rebuild the AC-4 first - then see if I can get the bias adjusted, but would like to confirm that with you smart folk who know these radios backwards and forwards.

I've got Garey's CD so that'll help a lot as I progress through trying to bring the radio to life. I did hear some receiver noise for a bit, then it went away. I'll do the usual and test tubes, caps, etc. but want to be able to let the radio run w/o toasting those nice looking RCA's sitting under the final cage due to no bias voltage getting to them.

Thanks in advance,
Eric
W9WLW

Eric,
If the AC4 hasn't been rebuilt, you are playing "Russian Roulette" until you do with those finals. I would rebuild it first before doing any more checking at all. Look on Harbach's site at the ES4AC4 rebuild "kit" that is built and pre-tested. All you have to do is take out old components and install it, and you are good to go for another 30 or 40 years. Then Hayseed Hamfest sells a re-cap kit that will replace all the electrolytics in the TR4C itself. No financial interest in either business, but a happy customer of both. Just my opinion and what I would do.

Steve -

A short to ground there would have just taken out R26, no problem for the 12BY7.

The 7 V on the Cathode means that the tube is drawing twice it's expected current, should be 3.5 V. Might be a leaky C32?

You may be seeing the 'collateral damage' from a shorted bypass cap on the Cathode or some other fault that turned the
tube on hard. Another popular failure here is a trimmer cap shorting to the chassis from application of a metal
screwdriver through those little holes. Shorts the +260 to ground through poor R26. Doesn't take long to smoke things.

That cap off the Plate lead is what I call a 'drum' cap. There's a bunch of the on the BAND switch, between wafers.
They're typically very low value caps, I suspect silver mica. Very reliable. That one is part of the neutralization
circuit for the Driver stage.

Is that a new 12BY7?? Your excess Cathode current may just be a gassy tube. Not even all "NOS" tubes are clean!

Sorry for the stream of consciousness, it's past my bedtime!

Turn the BIAS all the way negative to start, then reduce it to bring up the IDLE current. Excess plate current is very
damaging to the PA tubes!

Don:
Thank you for the quick reply. I have a re-build kit and will start in shortly on rebuilding the power supply. I wanted to make sure I wasn't missing something obvious on the bias setup is all. I will probably sell this TR-4c once it's running to keep the XYL happy unless I fall so deeply in love it that I can talk her out of me selling it. I'm more of a B-Line guy, and bought this TR-4c on a whim once.

Check the voltage at the grids of the finals. They're easy to find, as they're the pins with the wide strap connecting them. If the voltage is around -60V, then you may have dead finals. I've already tossed a pair of finals this week after assuming my problem was something else (something cheaper...) and it really turned out to be totally dead finals. Nearly identical symptoms, except I could get NO idle current whatsoever.

You will want to rebuild the power supply anyway, but checking the grid voltage is a quick check to see that you actually have bias.

No worries, Garey, I'm enjoying it.

The 12BY7 that was originally in the rig was really conducting hard - the plate voltage was down to 140V. I'm suspecting the short may have stressed multiple parts. You can really feel heat and smell the heat over the area of the driver. Guess it's time to change some caps. BTW, cathode resistor is within tolerance.

I'm mounting a small 12v computer fan on the top of the finals cage of my T4XB to blow air out of the xmtr.

I want the install to look clean and professional. Where is the best place to pick off 6v to run it at half speed? Should I plan on mounting a small terminal strip inside the chassis with a rectifier and cap for conversion from AC to DC?

Is it worth it to do the same with an R4C? Same questions and where would you mount the fan on the rcvr?.

Thanks!

I have a 220V fan connected to 120, it runs fast enough to cool the TX but doesn't make any noise. I would be reluctant to power anything external from the TX because I don't know if the power supply has the reserve. I just sit my blower on top of the cage with the finals. I put self-adhesive foam weather stripping around the edges of the fan. This acts as isolation for vibration (there isn't much anyway) and maybe increases the air flow a little. I also put protective screens on both sides of the blower.
The transformer in my R4B gets quite hot. If I put a blower like the above over it it stays cool to the touch. I think a very small blower would do the job. I don't know if its really necessary but I was brought up on the theory that equipment lasts longest when kept cool.
I got my blowers from All Electronics, they have a web site, but are not too long a drive from here so I just walked in and bought a couple of blowers that were on sale. I started with a 115VAC blower but could hear it even though my hearing is no long very good so I changed to the HV blower running at half-voltage. It works like a charm. I got the protective screens when I got the blowers. The weather stripping came from a local hardware store. I put

cord switches in the lines to the blowers.

For these little fans, there's ample power in the filament supply. Just make a half-wave rectified supply with about 100 uf capacitance and run the fan off that. If you tap off at 6.3V, you should have more than enough to turn a 12V fan at low speed - which is more than enough.

Richard's comment reminded me that I keep both my T-4XB and R-4B cool at the same time with one fan. My T-4XB sits on the right, with the MS-4/AC-4 to the left of it and the R-4B on top of the MS-4. The airflow from the final cage passes the right side of the R-4B, thus also keeping that normally hot side of the R-4B cool, as well.

Greg -

I don't know when it changed, apparently AFTER the last schematic at s/n 1000. I corrected it in my updated version of
the schematic for my CD, along with several other 'undocumented' changes. This has happened on other products; circuit
changes made late in production but never documented publicly. The 2-NT had several also.

I was using a 5 inch 115v blower mounted on rubber feet on top of both the T4XB and the R4C - sounded like the shack was a radio compartment in an aircraft.

If I had a 220vac fan I would use it. What I have laying around is a few of the 12v fans from old computer power supplies, the mounting holes of which match the perf pattern on the metal screening of the twins. So those are the candidates. I also have a bunch of larger 12v fans from cooling racks in computer equipment cabs that I plan on using in a cab that has a bunch of tube type receivers mounted in it.

     I have a 220V fan connected to 120,
it runs fast enough
to cool the TX but doesn't make any noise. I would be
reluctant to power anything external from the TX because I
don't know if the power supply has the reserve. I just
sit
my blower on top of the cage with the finals. I put
self-adhesive foam weather stripping around the edges of the

fan. This acts as isolation for vibration (there isn't much

anyway) and maybe increases the air flow a little. I also
put protective screens on both sides of the blower.
     The transformer in my R4B gets
quite hot. If I put a
blower like the above over it it stays cool to the touch. I

think a very small blower would do the job. I don't know if

its really necessary but I was brought up on the theory that

equipment lasts longest when kept cool.
     I got my blowers from All
Electronics, they have a web
site, but are not too long a drive from here so I just
walked in and bought a couple of blowers that were on sale.

I started with a 115VAC blower but could hear it even though

my hearing is no long very good so I changed to the HV
blower running at half-voltage. It works like a charm.
I
got the protective screens when I got the blowers. The
weather stripping came from a local hardware store. I put
cord switches in the lines to the blowers.

Richard -

The AC-4 has plenty of filament power left over when running a T-4X(any). It's designed to run the TR-4(any) with 5.5A,
and as the T-4X(any) needs only 3A there is plenty of room left to drive several fans!

The choice can be one of availability. Fans are very expensive if you buy them 'new', but are practically given away at
hamfests and surplus stores. Fans designed for 'odd' voltages are usually a real bargain!

Most any fan running at half it's rated voltage, provides more than enough air.

I have the same arrangement. The 115V fan I used at
first would cool the receiver too but the 220V fan running
on half voltage doesn't move quite enough air. The original
fan was just a little too noisy.

Steve, one of my T-4XC transmitters came with a 12Vdc fan tie wrapped to the back of the PA cage.The supply was the 12.6Vac filament voltage rectified with a 1N4000-series diode. No capacitor! The fan seems to run in the half speed range and is quiet. Cooling appears to be adequate.

I have done the same thing so I can't throw any stones at anyone else,
Steve.

My technique was to get a 220vac muffin fan and run it on 120vac. Just set
it on top of the cabinet. I use one with my SP600 receiver
to draw air out of the cabinet for better cooling. Works and is
inexpensive and no DC brushes in the motor.

Steve,
If you already have the 5" fans running on 115V on both the receiver and transmitter, try wiring them in series if the rigs are close together. I did that for years, and the particular fans I had would run slowly and not sound like a 747 in the shack. Especially if you already have them and they are essentially "free". Just a thought, but as others say, the power supplies will support the DC fans as well.

I had not thought about running two fans in series (Homer Simpson moment here) - good idea!

And thanks for the article link to the WB4HFN website - my only concern would be not using a terminal strip to mount the diode and cap; but other than that, great info. I'll have to check out that site.

Hi All

Yesterday at about 4pm local time I had just replaced the main filter caps and the other few electrolytic caps Powered it up to hear all was working well.
I tuned in 28.495MHz there was traffic, North America and Japan, it was no S meter signal and was a little hard to make out in the deep fades but was still readable 90% of the time.
Wanting to listen to the full conversation I powered up my modern receivers, JRC NRD-535D , Icom IC-R9000 and Tentec RX-340. These receivers are properly working and the RX-340 is a standards calibrated receiver.
I tried a lot of different combinations using a long wire , then a naturally resonate vertical antenna.
Basically it came down to the following.
My OLD Drake R-4A that uses valves received the 28.495 MHz stations when the other receivers had nothing there.
I could not beleive it myself, this $350 radio, that is over 45 years old works better that my most expensive and most modern receivers.
It was a really nice supprise.
It just shows you that good engineering based on stable physics will last the lenght of time. And of course when it is well built.

I am located about 150Kms west of Sydney In Australia.

Here is a question.
I run 240V at 50Hz, after about 45 minutes the power transformer gets VERY hot.
Does this happen with you guys running it at 110V 60Hz?

Regards To all

That's music to my ears, John!

I have an R-4C with the Sherwood mods, so it should do at least that well.

Drake, Collins and other manufacturers of that era obviously designed
and built their equipment to be used for the long run, not until the
next-newest model is introduced.

Here's where the R-4C places among the best of today:

http://www.sherweng.com/table.html

With a noise floor of -138 dBm, it's not shabby at all on receive!

That's interesting. I have my R4C, a couple of R390A's (1952 and 1967), an R388/51J3 and an Icom R70 - The R4C and Icom are about the same vintage, all older gear. The R4C (with GUF-1 and 2.1kc SSB filters), the R390A's and the R70 have all been gone through , the R388 has not been (yet). I have a long wire on a six way switch, so I can compare receiver reception. All five will hear the same signal. The R390A's seem , to my ears, to provide the best readability on weaker signals, but only by a slight margin over the R4C - it could be the difference between the 8" Hallicrafters cab'd speaker on the R390A's as opposed to the R4C speaker in the MS-4. It is not enough to prefer one over the other unless a signal is seriously down in the noise.

The bottom line: the R4C hangs right in there and does a great job.

The power xformer gets hot at 120 @ 60 Hz. I can remember testing power supplies years ago where we tried using xformers at 50 Hz with series primary windings and found that they ran hotter at 50Hz. We wound up getting ones optimised for 50 Hz.

The alternative for you, I think, would be to put another xformer in a buck configuration to lower the input to the primary to 220v. Still not optimised for frequency but at a less-stressful input voltage. You could also use a variac. Alternately, run a small cooling fan near the xformer.

John -

That is the worst case for the transformer. The higher voltage, combined with the lower frequency are both the least
efficient for the transformer. It IS rated for that, and yes, they definitely get too hot to hold your hand on at 120
VAC, 60 Hz. That said, I've been using and working on these receivers for just about 50 years now and I have yet to see
a transformer fail that was NOT taken out by a combination of a shorted filter cap - AND - an incorrect fuse. If it
would make you feel better a small bucking transformer wouldn't hurt anything, nor would a small silent fan blowing air
across the back of the receiver, just to get the heated air away from the area.

Topic: 18712 Message: 18718

What version of the R4A do you have :11 or 13 tube. I have one of the early versions #2550 - Dec 1965.

Typically, the transformer runs hot - at least mine does and I hear it's typical. Some install fans on top of cabinet over transformer to pull air out of cabinet and aid cooling.

I have both Drake A line and C line and a TR4cw RIT and I agree that all 3 receivers are excellent performers. I particularly enjoy listening to my R4C on 75 meter phone utilizing my HyTower vertical.

Cheers, Charles, KW6G.

It should be noted that the larger the fan the slower it needs to turn for the same volume of air. I have two of what I call "biga$$ server fans", 12V brushless DC fans, wired in series running on 12V on top of my L7PS. Can't even hear them running from a couple of feet away.

>For these little fans, there's ample power in the filament supply. Just make a half-wave rectified supply with about 100 uf capacitance and run the fan off that. If you tap off at 6.3V, you should have more than enough to turn a 12V fan at low speed - which is more than enough.
>
>Richard's comment reminded me that I keep both my T-4XB and R-4B cool at the same time with one fan. My T-4XB sits on the right, with the MS-4/AC-4 to the left of it and the R-4B on top of the MS-4. The airflow from the final cage passes the right side of the R-4B, thus also keeping that normally hot side of the R-4B cool, as well.

WB4HFN website has a treasure trove of information. Ron cleaned and tuned up my C-line last year. Great service and very reasonable prices. My rig works flawlessly now. Will compete with or beat any of the new mid priced ($4,000) radios of today!

That's not a theory, it's a fact. There's even a mathematical equation that expresses it.

For all those "these radios were designed to run without a fan" people the question becomes "why would you NOT want to extend the life of your equimpent?

Hi Charles

It is a 13 Valve unit, serial number 2914.

I had a R-4C, for me it was not as good, so I sold it off. It did not sound as nice as the 4A.
The R4A is not as stable as the later models but it is suprisingly sensitive.

I tried the fan but it only added about 10 minutes before the transformer got too hot to touch.
Since DRAKE designed it to work in that temperature range, who am I to change it.
I have considered changing the Transformer to a Torroid type, less heat, more efficiency and smaller size, but it would look totally out of place.
Thank you all for your temperature information.

Regards John

You might consider lowering your supply voltage with a variac. When Drake designed all of their radios, the typical line voltage was only 115 volt, in many cases it's now up around 120-125vac. Mine was usually hanging around 123vac.

With the higher line voltage, the filament voltage will also be higher, in some case up around 7 volts. Higher filament voltage = lower tube live and more heat.

I use fans on both my B-line and my C-line. I use the 3 1/2 inch 12 VDC fans and run them on 8 volts. They are very quiet and keep the units cool. I have one on each TX and RX sitting on the top and blowing air up, therefore sucking it out of the enclosure. I'm not running any fans on either of the AC-4 supplies.

On my L4, I am using the larger 5 inch muffin fans. I'm using 115 VAC fans that were sold by Rotron as "whisper" fans. They are about half the speed on the "normal" ones are are quiet. I have two of them on the L4 (one above each 3-500Z) and I have a third one on the L4PS. These keep the amp and power supply cool even during a contest as the L4 is my main station amp. It got a good workout last weekend in the ARRL DX.

This is a popular story, BUT if you look at the manuals for these radios, the Power Requirements are specified as
'120/240 VAC, 50-60 Hz'. Actually you have to go back to the early 1950's to find lower AC voltages, and then the
specified voltage was 118 VAC. The 1940's saw 115 VAC fairly regularly. Certainly a bucking transformer won't hurt
anything and will reduce the operating temperature. I don't really like a Variac, because most of them will actually
put out 10-15% ABOVE line voltage if turned up (accidentally).

Regardless, most equipment is specified as +/- 10%. All that aside, anything that reduces operating temperature will
extend component and thus equipment life. A small fan exhausting hot air from the area will greatly reduce device
temperatures in these units, and just HAS to increase Mean Time Before Failure, (MTBF).

18727. Drifting tone/freq(?) on my 4B Twins

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-19 15:09:02 UTC
From: <rsilvercat@...>
Topic: 18727 Message: 18727

I've been running my 4B Twins on 20 meters while my Ten Tec rig was at the factory for service. Recently I've experienced several QSO's where the other Op's tone wavered off frequency. I thought it might be the other Op's rig, but they reported my tone/frequency was wavering in their Rx. Since this has occurred several times, I'm relatively sure it's a problem in my rig.

The AC4 is still running on its original caps, the tubes are probably original to the rig (I purchased them, along with the original sales receipt, from the sole owner several years ago).

Does this sound like a power supply problem or is this a familiar characteristic problem that perhaps relates to a tube in the PTO stage? I'm slaving the T4XB off of the R4B's PTO.

From: <w5rkl@...>
Topic: 18695 Message: 18728

I cool the final stage in both my T4XB and T4XC transmitters with 12VDC muffin fans removed from blown computer power supplies. Each is powered by rectifying the 12VAC filament voltage using a half wave rectifier and an 8ufd 25VDC filter cap. Fan speed is slower than normal but fast enough to cool the final amplifier nicely and you barely hear it running. The fan is mounted outside on the rear rear wall of the final cage using short inch long 6/32 screws and nuts. I have it blow air into the final rather than suck air out of the final. I take a few moments every 6 months to check and, if necessary, blow out all dust that has collected on the final tubes and components.

Bob -

Yes, "A Family Affair - The R L Drake Company Story"

It has a good description of the early days, but kind of skips over the 4-Line to the 7-Line 'death spiral'. But then
I'm prejudiced! :-)

About half is stuff that probably came from the internet groups and their predecessors.

Bill -

Not much to go on.

Idle current correct? (70 ma)

What microphone?

Where was GAIN set?

What does PLATE meter reading kick up to?

From: Evan Rolek
Topic: 18729 Message: 18741

Bob, et. al.,

There are several factors at work here and this is not at all unusual. For example, I auctioned a new Drake CW-75 keyer, with manual, box, etc. and it sold for 1/3 of what the used ones, without guarantee or manual in unknown condition, were selling for on Upay, I mean Ebay, at the same time. I have some new Astatic 10DA microphone heads and the used ones are going for two to three times what I can get for my new ones. Some of the currently selling 2M mobiles go for something like $50 or more at auction, used, than what they are currently selling for new at the dealers; an amount much greater than tax and shipping charges. Obviously, some people have enough money that they don't have to look for the best pricing; I'm not that rich and have to be more discerning, hi hi.

73,

Evan, K9SQG

A friend of mine writes electronics texts and self-publishes them. I came across some folks selling his books on eBay for 3-4 times the price that you could buy the volumes direct from his company. I asked him why that was and he provided the seminal P.T. Barnum analogy - these guys would advertise his books, not even actually having them, then when a buyer (make that sucker) bought the book (why? Beats the heck out of me!) they would simply buy one from him and then ship it off to the sucker and pocket a hefty profit.

Amazing!

What percentage of ham radios up for auction include the claims “From and estate sale”, “I’m unable to test”, “lights up”, “As with all used electronics, sold as is” “I don’t know about this stuff”. Many of these sellers accidently capture parts of their electronic benches in the background of photographs, and they are almost all savvy enough to sell the PS in a separate auction. I honestly believe some of them intentionally use broken English to plant the perception that they may be a hapless seller, unaware of the great value of their find… at the “estate”. I suggest we let the fools feed off of each other and pledge to take our buying and selling of used equipment to the places where more respectable contacts can be found. We know the venues.

From: Robert Spooner
Topic: 18695 Message: 18745

Jim,

I'd be worried about the electronic noise that brushless DC fans would make. Can you detect any difference in noise level on your receiver when you turn the fans on?

> >
> >Richard's comment reminded me that I keep both my T-4XB and R-4B cool at the same time with one fan. My T-4XB sits on the right, with the MS-4/AC-4 to the left of it and the R-4B on top of the MS-4. The airflow from the final cage passes the right side of the R-4B, thus also keeping that normally hot side of the R-4B cool, as well.

Leon,

Very good idea! I have taken that approach. The few items I have purchased have been, in great working condition, near 10 out of 10 etc. Get the items and you can tell they haven't worked and couldn't have worked in 10 years. Then I spend 3 or 4 weeks working on them to breath life back into it. It's amazing how my opinion of a 10 is 360 degrees different than those folks!!!

It's usually better to pull air out than to push air in unless the system is designed for forced air cooling in the first place.

Was given an RV4C and what little information I can find on it tells me it should work with the TR3 and it does and is stable . the problem I have is that the dial reads I think 10 khz low . was on 3870 net wednesday night and the dial was on 60 a little more that halfway between 300 and 400 on the upper scale . could that be caused by the difference between the TR3 and TR4C ? also how does one read the scale ?

Andrew,
The manual for the RV4C is available at _www.wb4hfn.com_
(http://www.wb4hfn.com) also at _www.mods.dk_ (http://www.mods.dk) both would be free.
Yes the unit will work with the TR3.
The latter is a good reference to look at for what is available at that
site, I would use the former first as you don't have to sign to get material.

I believe the basic frequency EG 3.xxx on the TR3 is your controlling
factor as to what the remote unit is showing; Never played with one.

The PTO in the RV4c may need a slight manual alignment which has some
explanation on WB4HFN's site I am sure you will get other responses from the
list. The lever is slid over and you do a slight knob turn, for the
limited amount you reference. Garey K4OAH would probably be your best
information source.
73's and good luck, Carl WD8NHK

snips.

The RV4C will work with the TR3 after performing a slight change in the TR3's remote VFO plug/socket. See the following link for the simple VFO plug modification instructions.

http://www.zerobeat.net/drakelist/drakemod/drmod80.html
http://www.zerobeat.net/drakelist/drakemod/drmod80.html

The RV4C has "dual clear scale dials", just like the TR4C and the C line T4XC and R4C xmtr and rcvr. The TR3 has a single scale dial..

Good morning group,
I really enjoy reading the emails from everyone.
I have a R4C and T4XC that I purchased new in the early 1970's. They were in storage for awhile, and now have been in daily use for the last 3 months or so. I want to work split on 10 meters. I need to purchase a 39.1 and a 39.6 MHZ crystal for the T4XC.
Which of the crystal companies would be best to purchase from? I see International Crystal, Jan, and AF4K.com, etc. Has anyone had dealings with crystal purchases?
Thanks in advance for any advice.
Ed WA6WGS

Ed,

I've bought crystals from International Crystal over the years. Why? When I call, all the woman wanted was the model number of the gear and she had the specs. With a lifetime guarantee, I didn't see any reason to go elsewhere. Delivery was always faster than what was quoted.

73,

Evan, K9SQG

Ed,
International in Oklahoma City is still owned by an amateur, still has the cutting instructions for Drake and will deliver a an accurate crystal that will work in your Drake well or they will cut another free. They may be a bit more expensive, although I doubt it, and usually deliver well before the time they tell you on the phone. I believe the lady's name is Sarah on the phone, but when you tell them it is an amateur crystal, they know who to give you. I don't have the number handy, but you can Google International Crystal and it will come right up. They are around $20 each and well worth the price.

Andrew -

Yes, the RV-4C will work fine with the TR-3. There is a modification needed in the TR-3 to allow the RV-4C to disable
the TR-3 PTO, otherwise when the RV-4C tries to control the frequency, BOTH PTOs will be active. Not good!. If the mod
has been made, if you unplug the RV-4C from the TR-3, the TR-3 will be 'dead', as in no PTO. If the TR-3 works with the
RV-4C unplugged, you need to make the mod. There is a jumper between Pins 2 and 8 on the RV connector on the bottom of
the TR-3. That jumper must be cut. If you want to use the TR-3 then without the RV-4 connected, you'll have to either
replace the jumper, or make up a 'dummy' plug with pins 2 and 8 connected.

The "C" dials work a little different than the earlier single dial radios. There will be one or two flat metal 'levers'
on top of the PTO gearbox. If there is only one, depressing it will free the kHz (000-500) dial which can then be
aligned with the actual frequency. You can tune in the Calibrator with the RV-4C in RECV control, depress the lever,
and rotate the dial to 000. This is a little difficult to do without removing the RV-4C from the cabinet, but once done
it shouldn't change. IF there are two levers on the gearbox, the 'other' one releases the 100 kHz dial.

Hi Don,
Thanks for the comments. I was leaning towards International Crystal. If it was for my old Globe Chief with an FT-243 holder, I would get out my sand paper and go to town to get it from 80M to 40M.
At that frequency want to make sure the crystal will work in the Drake oscillator circuit properly.
Have a good one 73's

I know about and have already cut the jumper and made one on a dummy plug to put in the rv socket when the RV is not connected
my problem is that the frequency is off on the RV4C dial . on 75 metres receiving the 3870 net it comes in on 3860 for a 10 khz difference . on 40 it is a little different only off 8 khz . that is a little puzzling , I would expect the error to be constant on all the bands or am I wrong about that ? have not checked the other bands yet . don't want to make it worse by doing something stupid . also I have not really figured out how to read the dial . I think you have to add the band switch frequency to the dial reading to find the station .

Topic: 5900 Message: 18761

The VFO operates over a set frequency range between 4.999Mhz and 5.500Mhz and that frequency range does not change regardless of the band switch position. Believing the VFO frequency tuning range changes between bands is a mistake many inexperienced hams tend to make. If you review the TR3's operators manual the signal processing in both transmit and receive is discussed. If you do not have the TR3 manual, click on the following link to download the manual.

http://gmcotton.com/Ham_Radio/MISC%20Manuals/Drake/Drake_TR3%20HF%20Tranciever_Service%20Manual.pdf http://gmcotton.com/Ham_Radio/MISC%20Manuals/Drake/Drake_TR3%20HF%20Tranciever_Service%20Manual.pdf

Go to Chapter VI, page 21, and study "THEORY OF OPERATION" along with the block diagram on page 24.

The RV4C VFO manual can be downloaded at

http://www.wb4hfn.com/DRAKE/DrakeManuals/RV4C/Manual_RV4C.htm
http://www.wb4hfn.com/DRAKE/DrakeManuals/RV4C/Manual_RV4C.htm

The RV4C has 2 dials, a front and rear dial. The Rear dial is marked off in 100Khz increments with numbers starting at zero through 500. The front dial is marked off in 1Khz increments. Each front dial small "tick mark" equals 1Khz and each number represents 10Khz starting at zero through 90 then zero again.. Therefore, if the band switch is set to 7.0, the RV4C VFO FUNCTION switch is set to RCV/XMT, the rear dial is set between 100 and 200 and the front dial is set so the 50 is in line with the RV4C's window RED vertical line, the frequency for transmit and receive is 7.150Mhz. Once you get the hang of this you should have no trouble using the RV4C VFO.

With the RV4C connected to the TR3 and the RV4C FUNCTION switch set to REC/XMT, the RV4C controls the TR3 transmit and receive frequency. Setting the R4VC FUNCTION switch to OFF, the TR3's internal VFO controls the TR3. Setting the RV4C VFO FUNCTION switch to RCV, the RV4C controls the TR3's "receive" while the TR3's internal VFO control transmit. Setting the RV4C FUNCTION switch to XMT, the RV4C controls the TR3 transmit frequency while the TR3's internal VFO controls receive.

Thanks I know the tuning range does not change with the bandswitch . I have manuals for both and with the TR3 controlling the stations are approximately where I expect to find them . The RV4C is 10kcs low on 75 metres and 8 kcs low on 40 metres . as an example the 3870 net was being received on 3860 with the RV4C controlling and 3870 with the TR3 controlling and the 7285 and 7290 nets were being received on 7277 and 7282 with the RV4C . just don't understand why there is a 2 kc difference on the different bands . the error should be constant I would expect .

Likely the appropriate band crystal is the offender; there's one for each band. Others will know the synthesis scheme used; I joined the party at TR-7!

18764. T-4XC problem

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-21 02:37:55 UTC
From: Robert Logan
Topic: 1054 Message: 18764

My T-4XC recently developed a problem of unkeying quickly on SPOT and when sending a long dash on CW transmit. It only occurs on CW. SSB and AM spot and transmit are as per usual. The CW DELAY pot has little effect on how quickly it unkeys on SPOT or the long dash. In addition, there is no sidetone at any settings of the antivox, VOX gain, or CW delay controls. The lack of sidetone occurred at the same time as its unkeying quickly in CW SPOT or CW transmit. When sending faster CW, the rig keys, stays on, and drops out as it should.

I've substituted 12AX7s (V9) and antivox cables but the problem persists. I'm thinking maybe C107 or CR15 might be the culprits but I don't why it would be fine in faster transmissions if they were bad. Maybe it's even a dirty relay?

Any advice would be greatly appreciated. Bob, NZ5A

Andrew -

If you look at the block diagram in the manual, and read the 'Theory of Operation' section, you'll see that on 75M the
PTO at 5.2 MHz is mixed with the 9 MHz CAR OSC and the difference is the 3.8 MHz signal. On 20M the sum mixer product
is the 14.2 MHz signal.

On 40M the BAND oscillator runs at 21.5 MHz and is mixed with the PTO, resulting in a difference frequency of 16 MHz
which is then mixed with the 9 MHz CAR OSC, resulting in the 7.0 MHz output. So your 21.5 MHz crystal is ~ 2 kHz off
frequency.

Bob -

V9 is converted to a phase shift audio oscillator in CW. This is the SIDETONE, and the tone used in TUNE mode. IF TUNE
works ok, the the problem is most likely a shorted CR15. Less likely is R84/85. The reason it pulls in briefly is the
C115/CR17 network which 'yanks' the VOX on quickly to preserve the first 'dit' or the first syllable on SSB by sending a
pulse of current directly to the Grid of V10B.

I haven't noted any. Where I have seen noise problems in other applications it was not radiated, but rather conducted noise induced into the power circuits. I have seen this in noise bars introduced into a high end security camera and auduble noise in a UHF low power radio system. In both cases engineering resolved the problem by adding ferrites to the power leads of the fan.

Gary, thanks for the guidance.

TUNE works in the sense that I can peak the output with the RF TUNE and PLATE controls as indicated in an S meter on the R4B but there is no output showing even in a QRP wattmeter (which is known good). When I switch to CW and send, there is full normal output on the wattmeter (this time using the W4 wattmeter (also known good). If I try to hold a long dash, it still drops out quickly but sending a string of characters like my call or RST shows full output.

Being able to get full output when sending CW but no watts out in TUNE tells me something but I don't know what exactly. Adjusting GAIN does vary the output in both transmit and TUNE (on the S meter).

Another in this fine group suggested it might be a bad 6EV7.

V9 is converted to a phase shift audio oscillator in CW. This is the SIDETONE, and the tone used in TUNE mode. IF TUNE
works ok, the the problem is most likely a shorted CR15. Less likely is R84/85. The reason it pulls in briefly is the
C115/CR17 network which 'yanks' the VOX on quickly to preserve the first 'dit' or the first syllable on SSB by sending a
pulse of current directly to the Grid of V10B.

OK. It's NOT V10. Sounds like the V9a audio oscillator ain't!!

The ~ 1kHz audio note generated here is 'keyed' by CR15, and amplified by V9b. Output to the BAL MOD for TUNE operation
is from the Cathode of V9b, and the SIDETONE comes from the Plate of V9b.

A shorted CR15 would give the symptoms you describe, as it would prevent the audio signal, IF it's there, from reaching
V9b. The V9a oscillation is controlled by switching in a phase shift network, R97, 98 and 99 along with associated
capacitors. Here the most likely problem is dirty switch contacts on the FUNCTION switch, on the front side of the
fourth wafer from the panel.

The signals out of V9b are MISSING, either because V9a is not generating them, or they're being prevented from reaching
V9b, most likely by a shorted CR15.

Guys,

as the subject line says, I picked up a SPR-4 at a hamfest the other day.

It's in good shape, front panel is nice, and there doesn't seem to be any extra holes in the cabinets
It does work...to a fashion
The PTO is all screwed up. There is no dial skirt. The last owner (The guy that sold it to me) oiled the pto gear with singer sewing machine oil.
The stuff flows out of the chassis. There is a problem with the gears as you have to make one complete turn of the knob to get the plastic dials to move. The pto moves, just not the dials.

good news is it is full and i mean full of crystals.

so, were does one begin to fix this mess with the PTO?

How do you remove the oil from those nylon gears ?

What A project I have now

Mike:

It’s basically the same as any other 4-line PTO so you can get very good instructions on removal and cleaning of the PTO from WB4HFN’s web site. Only 3 wires and 3 stud mount nuts/locks to remove and they are not too bad to get at in the SPR-4. I’ve just been through 3 of these! One of them twice! You will need to remove the front panel and dial window to remove the PTO.

I use 99.9% alcohol from the drug store to wash the bits and pieces. Windex has worked for me on the dials themselves though some guys are not in favour of that. It doesn’t remove the dial markings. Be REALLY careful removing the little brass rivets – there will be two on earlier serial #’s and 3 on later units. The ones with two brass rivets will require VERY careful removal of the plastic dial gear which is attached to the brass shaft as it has two plastic posts which have been melted slightly to hold the the 100’s dial on there. You want to leave enough post that later you can set the dial on there in the right place, then either re-melt slightly or use a bit of clear silicone as a tiny dab to hold it place. The later dials with 3 rivets don’t have that problem, if memory serves me right.

Also, be very careful of the orange coloured fiber washers- they break easily. You may see only one of those, right up against the PTO housing – it’s the last piece that comes off, and the first to go back on. Clean everything well with a small brush and the alcohol.

Take pictures as you disassemble to help you get it all back in the right place. I-phones work great! PTO’s are known to have different numbers of thin plastic washers to help keep the dials apart. Early ones had none.

Make sure the 1/4” shaft is VERY smooth – I use a bit of 1500 grit emery on it to make sure. I have found some with nasty little burrs under there. You may need to lightly sand the inner part of the brass shaft and the nylon gears as well. That first brass/nylon gear piece should spin really easily on the PTO shaft when you snap it with your fingers.

I swab the front bearing with Q-tips (or better yet, sponge – tipped swabs) soaked in alcohol until I get rid as much of the old red grease as possible. Usually takes 3 or 4 double ended swabs. Then re-grease only the bearing lightly with white lithium. I also use the swabs to clean up the threaded shaft as well.

I usually set the “yoke” at mid-range on the threaded shaft and align the dials for 250 on re-assembly. That gets me within 25 khz or so for final calibration once everything is back together. Avoids powering it up while out of the chassis but of course you could do that and read the frequency on a counter. Inevitably something gets bumped when going back together anyways.

Hope that helps – “some times you just have to go for it!” (from “The Dish” – my favourite movie)

yes, garey, the rubber clutch is rock hard

but that being said, you REALLY have to twist the main tuning knob to get
the pto shaft and the dials to move.

the pto moves okay, it's the gears and dials that are quite stiff

It could be a lot of things. Without more detail about
the nature of the distortion its hard to tell. You may be
able to monitor your signals on your own receiver. Listen on
headphones and see what you are getting. Also, do you have
an oscilloscope capable of working at the transmitted
frequency? If so the wave form can tell you a lot.
Post more detail and we will analyze the problem.
Also, get more signal reports, maybe the fellow complaining
has a bad receiver.

Remove the entire PTO from the chassis. Yes. This means removing the front panel. It's not hard - really.

There. Now that you're past this stress, read on.

Refer to the WB4HFN article about making the C-Line PTO "smooth and silky". Before you get there, you will need to take as many parts as you can from it and thoroughly scrub them in Simple Green, Crud Cutter or other serious surfactant, to remove all petroleum from those Nylon gears.

Note that there are at least three variations in the assembly methods of the C-Line PTO's. Document what you take apart with copious digital photos and share them with the group when you're done.

This is not rocket science, but it does require some attention to detail.

I had an SPR-4 that I could only have hoped had merely a mechanical problem. I was fortunate in that I was able to piece everything together, thanks to K9SUL lending me another receiver to copy from. Sometimes, seeing is the only way of believing. Put out the call if you need one to use as a known-good example. The list will respond!

I'm looking for a nice Drake RV 4C to go with my TR 4C. Wonder if anyone has one they would like to sell. Please reply off list.
Thanks,

Lawrence, WA4BHK

A lot of people like Lee Lagoon Blue, #172 See;
http://www.leefilters.com/lighting/colour-list.html

Lee has a dealer search on the above web page.
Somewhere also they detail the various thicknesses
available. I have not priced lighting gels for too long to
know what they cost now but in the past they were pretty
cheap.

Bought some of this on eBay. Wicked cheap. Shipping included, and the price was about 5 bucks above the shipping charges. Cheap enough.

If you need enough for only one rig, email me off list. I'll send you enough for 6 bucks to do your rig. That covers priority mail, IIRC.

The bad thing about the original with yellowing of the dials and such the color comes out more green than blue. You kinda need to offset for that.

Try your local toy hobby store. I picked up there several times for just over a dollar a sheet of clear PVC blue thet is .010" thick made by Midwest Products and called Raboesch super sheet. They come in all different colors and work just excellent.

The dials don't yellow as much as the 'white' light shield and the 'white' diffuser. Bright white paint and a new
diffuser brings you back to the 'original' blue with Lee Lighting 172.

Hi Steve,

I've had the PTO removed & disassembled from my T-4X transmitter several times here, & doing so most certainly never necessitated anything as drastic as the removal of the front panel...

It CAN be done strictly as an "inside job", as long as you unsolder the 3(?) wires linking the PTO to the rest of the transmitter (they come out of the PTO enclosure at the front / bottom of the shield can), and you remove the tubes immediately behind the enclosure to facilitate pulling it back once all of the fasteners are removed (I believe there are 4).

You can see the progressive steps required in removal, if you study it logically & proceed accordingly.

But why throw the complication of front panel removal into the mix, too...?! It can be a scary enough / daunting assignment on its own...

It certainly can be done without removing the front panel, as Eddy says.

The only caveat is to take extreme care to avoid scraping the dial discs on the chassis edge as it comes out.!

Not wishing to start and argument over this but I have never had much luck getting the PTO out of a dual-dial rig (C-line/SPR-4) without removing the dial window glass. The PTO shaft gets hung up on it as you try to get the PTO studs up and out of chassis, then the dials get in the way etc.etc. With the window “glass” removed, it’s a piece of cake. Now any later series C-line should have the window glass mounted between the front panel and the sub-panel, requiring removal of the front panel to get at its mounting screws.
I can get the SPR-4 front panel off in under 5 minutes. Sure makes things a lot easier and as Garey says, less risk in scratching the dials.
It has been a long while since I have had a single dial (4B-line-/4A-line) PTO out so maybe things are a bit easier with those? If I’m cleaning up a newly acquired rig I usually have the front panel off anyways for a full cleaning.
YMMV!

Actually, to get at all of the gears to clean them, you need to remove the entire unit.

These rigs are old enough where removing the front panel is a good thing, anyway, since you can clean it much more thoroughly.

I can get a front panel off in five minutes. There's no fussy orthoscopic surgery to put up with, either. All screwdriver work, aside from removing the wires from their connections underneath! (clip those rather than desoldering - the wires won't turn into melted messes that way).

YMMV...

HI Eddy:

How are things in the land of ice and snow and wind and freezing rain? I could probably ask Garey the same thing – three weeks ago I flew over NC and there was snow all the way to the South Carolina border!

Getting the PTO can off is certainly a different story – pretty easy to do in most rigs without surgery. I would think the R-4C with optional NB would require removal of the NB and maybe even the outboard mount. Fortunately most of my PTO adventures have centred around the gears, the dial;s, and the PTO front shaft bits.

I am still not happy with the PTO in one of the three SPR4's I have been working on the past couple of months. This one had damaged PTO mechanicals; fixed the main issue with it but looks like someone modified the front bearing area somehow – there's a washer in there that is preventing proper tightening of the shaft against the bearings, so there is a slight bit of up/down play that I can't tweak out, as if the washer is riding on the bearings rather than allowing the shaft to "centre up" between the bearings. Tightening the shaft just locks it up. I am thinking of just replacing that PTO with a spare.

As the PTO will need to come out for the third time I'll run a little experiment and see just what I can do without removing the front panel and/or the dial glass. I'll report my findings back here. There is plenty of room behind the PTO in the SPR-4 so it's a good one to experiment with. Of course things may be different in rigs with less open real estate.

Just curious if anyone on the list is planning on attending the Hanging Judge Hamfest, in Ft. Smith, AR, the first weekend of April?
I expect to be there, selling some 4-Line gear, and assorted boat anchors, as well as some modern VHF/UHF gear. If anyone thinks they might be interested in going, here is the website:
http://www.hangingjudgehamfest.com
I am told by members of the sponsoring club, that there should be a great deal of classics, including Collins gear available.

Garey:

Haven’t lost one for years! And managed to find a very close replacement fiber washer at Home Depot many moons ago, just in case. They are in my parts bin. I’m surprised Donnie, or Chris, or Mark haven’t got those in their stores yet. Maybe they are too easy to find?

Frankly, the things that usually give me grief are the older non-setscrew knobs and that little spring steel piece that sits inside and breaks in half, half the time. Like the washers they have an automatic homing device in them that seek out the crack between the floor and the bench! Sorta like the auto-migration of that antenna switch on the side of the TR’s.

Now, those little brass rivets on the dials.....!!!! Hoo boy!

>
> Getting the PTO can off is certainly a different story – pretty easy to do in most rigs without surgery. I would think the R-4C with optional NB would require removal of the NB and maybe even the outboard mount. Fortunately most of my PTO adventures have centred around the gears, the dial;s, and the PTO front shaft bits.
>
> I am still not happy with the PTO in one of the three SPR4's I have been working on the past couple of months. This one had damaged PTO mechanicals; fixed the main issue with it but looks like someone modified the front bearing area somehow – there's a washer in there that is preventing proper tightening of the shaft against the bearings, so there is a slight bit of up/down play that I can't tweak out, as if the washer is riding on the bearings rather than allowing the shaft to "centre up" between the bearings. Tightening the shaft just locks it up. I am thinking of just replacing that PTO with a spare.
>
> As the PTO will need to come out for the third time I'll run a little experiment and see just what I can do without removing the front panel and/or the dial glass. I'll report my findings back here. There is plenty of room behind the PTO in the SPR-4 so it's a good one to experiment with. Of course things may be different in rigs with less open real estate.

Hi Peter,

Thanks for thinking of us poor easterners out here locked in the throes of what feels like a permanent new Ice Age...!

This past week was a remarkable change from before in that there was no new snow, & the temperatures actually reached the high 30's on the "F" scale---but the currently high winds fortell of colder weather to come, with a drop all the way to 5F by Friday (sigh!).

My only trouble with Drake PTOs has been with (A) poor solder joints, and, (B) value-changing of some of the components. But considering the fact that these things are fast approaching the half-century mark in terms of age, I'd say that approaches the level of "...simple maintenance", & little more!

Enjoy working on those rigs, Peter, & celebrate the fact that you have the ability to do so: we are fast becoming an "extinct species" here, as throw-away appliances take-over the realm of Ham radio...

Joining this discussion late I want to point out that I recently repaired a stuck dial in an SPR-4 and documented my actions on this list. Peter, others and I had a fairly long discussion about what I encountered, and other SPR-4's. You can find it in the archive.

Geoff.

I am convinced there is a parallel universe with enormous mountains of screws, nuts, socks, springs, collar buttons, nickels and dimes, twenty dollar bills, and etc, etc. It is led to by a one-way portal that is invisible to humans (but maybe not cats). I also think I probably have fairies in my back yard; they get curious about small objects and borrow them to investigate. I often find these later in places I KNOW I have already looked. We just think we live in a normal universe, if we saw it for what it really is we would run screaming like Bette Davis in "Jezebel".

Of course the cats can see it. That's a given. Do you really think that they are FROM this planet?

The fairies have that Swan (Siltronix) VFO dial that went missing here several years ago. I have not been able to convince them to return it yet. I think they have that fiberglass rod that I was looking for yesterday too. I suppose maybe they needed it to pitch a tent.

You're both wrong. That 1/2" above the floor where small parts instantly vanish into thin air is not a warp zone. It is the "Flourth dimension".

Robert,
Several times I've accused Garey of being a retired professor from an engineering department of some college (MIT comes to mind). I have learned more about how receivers work, even if they're not Drakes, just from his explanations....something I could stare at a schematic all day long and not come to the same thoughtful conclusions!!
A real GEM on this list!!

Dang, you're clear! You must have been a professional technical writer at one time.

Thank you very much, Gary. Lots to check on but clear as a bell. Now if I could only find CR15....

I need your CD. Skinflint that I am, I gotta go ahead, unglue my wallet, and order it. Bob, NZ5A

Sent from my iPhone

On Feb 21, 2014, at 9:22 AM, Garey Barrell <k4oah@...> wrote:

Bob -

OK. It's NOT V10. Sounds like the V9a audio oscillator ain't!!

The ~ 1kHz audio note generated here is 'keyed' by CR15, and amplified by V9b. Output to the BAL MOD for TUNE operation
is from the Cathode of V9b, and the SIDETONE comes from the Plate of V9b.

A shorted CR15 would give the symptoms you describe, as it would prevent the audio signal, IF it's there, from reaching
V9b. The V9a oscillation is controlled by switching in a phase shift network, R97, 98 and 99 along with associated
capacitors. Here the most likely problem is dirty switch contacts on the FUNCTION switch, on the front side of the
fourth wafer from the panel.

The signals out of V9b are MISSING, either because V9a is not generating them, or they're being prevented from reaching
V9b, most likely by a shorted CR15.

Bob, NZ5A
Bob, the CD for your Drake will be the second best investment you can make, following the Drake of course! I resent purchased one from Gary and it it just packed with valuable info and *color* pictures. This is an unsolicited comment, just has helped me on my TR-4 immensely an thought the "Thank you Gary" was over due!

I think its available from any of the larger photo
equipment suppliers. B&H came up in a google search and I
suspect Freestyle has it too. A 24x21 inch sheet is
probably a lifetime supply. Its even possible you might be
able to get a large enough sample from Lee to do a dial and
meter.
BTW, I love the names of some of the colors.

I got a chunk from an eBay seller, cheap and easy. Interestingly, there are two flavors of #172, the Lee and the Rosco E-Color. You can see both at about the middle of the page below, generated by the hex codes of the online samples taken directly from the respective web sites.

I keep going back and forth between the two spellings.. I think you are right though, Richard... "The Floorth Dimension" it is!

Every time I say it, I hear the Twilight Zone theme and introduction-

"There is a a floorth [5th] dimension beyond that which is known to man. It is a dimension as vast as space and as timeless as infinity. It is the middle ground between floor and bench, between science and superstition, and it lies between the pit of a man's fears and the summit of knowledge. This is the dimension of lost parts. It is an area which we call, ..." We'll, you know the rest.

The easiest place to find the gel, is at any theatrical lighting supply shop. BTW..Lee makes a heavy duty sheet of this color as well....I am pretty sure that is what my sheet was, that I purchased..locally, for $5.00, I think it was. pretty durable stuff.

I keep going back and forth between the two spellings.. I think you are right though, Richard... "The Floorth Dimension" it is!
There is a pun hiding here...
I think there are several parallel dimentions: the one partly occupied by cats; the one things vanish into when dropped off the table (I have seen them fade away as the fell); the one reported on by TV news. Actually _nothing_ ever happens, it's all made up by the boys in the back room. If they told you that nothing was happening you would have to turn off your TV and go outside (except in the north-east where entropy is increasing very rapidly).

Easy is relative. We didn't have anyone here in Lincoln that carried it, so I would have had to either try to chase down someone who happened to have some on hand or (maybe) drive to Omaha. Ordering from a reputable eBay vendor was only a few mouse clicks worth of effort and I didn't even have to leave my chair. What I got delivered to my door was a big sheet packaged in a sturdy shipping tube that I use to store the extra. As I recall, it was only around 8 bucks. I don't know if it's "heavy duty" or not, but it scarcely matters in this application. This stuff leads an easy life in front of a puny radio lamp.

My statement about entropy may not be correct, I meant
that the temperature is approaching absolute zero and will
eventually get there. You need to have a good parka and
thermal underwear and something to cover your face and ears
if you go out. Leave the snow where it is, better to turn
on the TV and let the cable news people shovel it.

Problem found. The radio Gods have decided to give me a Challenge. I discovered that the cailibrator signal was about S9 as normal. After tracing things everywhere I found on the back panel where to RX antenna ia jumpered between two RCA jacks had never been soldered from the factory. The contact on the back of the RCA plug was still virgin with the wires neatly wrapped through the solder hold but no solder added. The radio has operated all these years and no receive problem had shown up until today. Obviously the radio Gods moved the wires overnight to ruin my day as it was working when I shut it down last night. Who would have thought this would happen at the same time I go an antenna short from the deceased squirrel.

Guess this one slipped by Drake QC

Gary K4MT.

I've found wrapped but unsoldered connections several
times, once in my R4B and a couple of times in General Radio
instruments, and elsewhere. All of this stuff got through
the manufacturer's QC and worked for decades.

Lee describes their lighting filters as heat resistant,
see their web page. These filters are intended for use on
high powered motion picture and stage lighting instruments
including carbon arc (not sure they are used any more) and
xenon arc lamps.

Yep, it's probably only relevant if you want to change the color of the glow from the finals. The lamps this gel is used with are high power stuff, and generate a lot of heat. Much more than a #47 or #53. The large spots have cooling fans in them (pulling air OUT, I'm sure). The gel also has to hold up to being rotated in and out quickly to change colors during performance.

I've actually found that I need to stack two layers of 172 to get closer to an original filter. That's my "heavy duty".

Agreeing with me is good for your blood pressure.... :D

Goes to show you what my dad, although never a ham, taught me early on: Make a good mechanical connection before soldering. Yes, a bit difficult to do with PC boards but for point to point wiring like the 4-lines, etc., a "point" well taken.

Yeah, right......

From Lee's site

172 Lagoon Blue
Accurate and consistent colour from batch to batch.
Available as a High Temperature filter.

"Designed to withstand hot light sources"

Does NOT indicate whether it's 'mechanical' (melting) or perhaps more resistant to fading.
The price differential is
small enough that it's worth trying. ($8/sheet v $10/sheet from one dealer)

Possibly both. Fading and melting would both be inherent risks in bigass lights.

Wrap a chunk around one of your JB6s and let us know how it holds up. Or maybe a 3-500z. Now there's a thought. Finally, a way to get a blue glow from an L-4B!

It means both. While stage lights may not be very high power motion picture lights very often are, typically 2 kw to 10 kw incandescent and maybe 20+ KW high pressure xenon arc lamps. They get very hot so the gels must be resistant to melting and to fading.
Someone posted that he needed two layers of #172, its possible Lee makes a gel that is equivalent. They have spectral transmission charts for all the filters on their web site. Actually, in lighting practice its not at all unusual to use more than one filter on a lamp.
The other big supplier of lighting filters is Roscoe. I don't know the equivalent Roscoe filter but I think they have a filter chart on-line too. Some filters are common and have the same name among suppliers, for instance "no-color straw", this is used on "daylight" carbon arc lamps to approximate sunlight, there are others. The lighting plot for a stage show will usually detail the filters and diffusers to be used on the lights, usually be the manufacturer, name, and stock number.
My memory of Drake gear when new is that the dials

looked phosphorescent.

18849. L4B Soft Key Interface

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-23 19:07:33 UTC
From: Bill Gaines
Topic: 18849 Message: 18849

I am spending part of the day installing a couple of modifications to my L4B and have a legitimate question for those in the know. When my station is complete I will have a “modern” station set up complete with amplifier and a completely restored C-Line and L4B amplifier. I purchased the inrush modification for the amp as well as the soft key modification but before I go ahead and install the soft key mod I though I would find out the answer to this question.

I planned to install the soft key mod just in case my “modern” amp went out so I would still have an amp. However, if my modern amp never goes out and I want to always use the L4B with the T4XC will I be able to do so after installing the modification. Or should I just wait until such time I may need the amp to run with the modern rig then install it?

The short question here is can I still use the L4B with the T4XC after installing the SK401 soft key interface?

Thank you

Bill AD8P

Quick answer is yes, Bill. The T4XC gives a set of relay contacts, so could care less what it sees. Install it if you like, if it activates by a switch to ground.

Bill,

Typically a soft key interface will enable the linear to be used with any rig, solid state or tube. I using the UKA-2 interface on my L4B and L7. Installation per the presentations at the Drake Forum at Hamvention in past years, might even have slides at the WB4HFN website.

To add to Don's comment, some of the newer rigs have a selectable interface, MOSFET or relay. However "those relays" have very low ratings in terms of how much voltage and current they can handle, typically not enough for the vintage linears.

You need to be clever with these advanced aliens. It is imperative that you catch them unawares, otherwise they will retire to their private club on the Planet of Lost Socks until the time has passed. The trick is to bring the kitty carrier out a few days ahead of time and leave it in a conspicuous spot. She will quickly get used to it as just another thing around the house. Then when the time comes you can just scoop her into it and go. Works every time.

Well, that’s the whole idea for using the MOSFET, higher switching capability. On my Icom IC-7600 in that configuration the rating is up to 250V at 200mA which I’m gonna guess should be sufficient to switch just about any amp old or new.

18857. TR-4 and 10 meter trouble

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-23 20:39:54 UTC
From: Marco B.
Topic: 18857 Message: 18857

Hello folks,

the radio is fine except for 10 meters. No matter which of the 3 positions I set the band on, the RF Tune needs to be all the way clockwise (#10) in order to here white noise. It seems to drift a little too.. again only on 10 meters. Is there anything I can do/check to fix this?

Marco

18858. Re: L4B Soft Key Interface

bill and the group,

I have a small pcb that mounts inside the l4.

It's going to be cheap, i have a few prototypes left.

pop me an email and I'll send some photos of the installed pcb inside the L4

18859. L4B Relay Connector

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-23 21:09:49 UTC
From: Bill Gaines
Topic: 18859 Message: 18859

I need a couple of the two pronged relay connectors; one for the AC4 and one for the L4B. I also need 4 of the rubber covered screws used on the MS4 that hold the AC4 inside. I know I could anything but at this point I have spent good money having the C-Line refurbished and have rebuilt the AC4 and power supply for the L4B I might as well make everything right. I have found the rubber covered screws at one vendor but am just trying to get everything from one source. Just let me know off line. No need to clog the reflector with this info.

I am anxiously looking forward to getting this stuff on the air.

If you find a source for those 2 pin connectors, please let us all know. So far nobody (myself included) has been able to nail down anything to secure NOS stock or have them custom made.

18862. TR-4C meter zero

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-23 21:25:08 UTC
From: k7mks@...
Topic: 18862 Message: 18862

With no incoming signals, including crystal calibrator, and with C-130 adjusted for equal sounding "white noise" when switching between
Lower" and "Upper" I am unable to zero the S-meter in both sidebands. It will zero with one or the other and then the other is off by 1 to 1 1/2 S units or so. I can adjust C-130 so the S- meter zeros in both sidebands but then the "white noise" has a different sound in each sideband.

My other TR-4CW/RIT works as it should in all respects to S-meter zero, C-130, and "white noise": sound.

I'm convinced I'm overlooking something.

Either building connectors with pins on a piece of phenolic or plastic, or replacing them with something else- commonly a RCA connector.

You need to be clever with these advanced aliens. It is imperative that you catch them unawares, otherwise they will retire to their private club on the Planet of Lost Socks until the time has passed. The trick is to bring the kitty carrier out a few days ahead of time and leave it in a conspicuous spot. She will quickly get used to it as just another thing around the house. Then when the time comes you can just scoop her into it and go. Works every time.

From: Steve Wedge
Topic: 18857 Message: 18865

The tuning for the 10m band is done with one set of coil adjustments, for all three segments. In the manual, they have you peak the coil at 29.7 MHz or thereabouts, with the RF TUNE on "9 3/4" - I.e., almost to 10. Presumably, this allows the single adjustment to work over the entire band. It may also have something to do with spectral purity, so I'll wait for Garey to chime in on this. I have had better results tuning it a couple hundred kHz lower.

If you're peaking on "10" on all segments, there's something wrong with the 10m tuning. Someone before you may have been in there with a "golden screwdriver" or they were running it on 11m. Try doing the adjustments for 10m per the manual first.

Depspite the conventional wisdom about problematic PIN diodes, I have not had any bad ones cross my bench yet. It is, however, more common than I would have thought to find a TR-7 that has been paired with an R-7 during it's life and has had that jumper between the RCA jacks cut. So that's always my first check now. My "spare" TR-7 actually came to me with an external jumper in place, which doesn't happen very often. Gary's problem was a little more unusual, but still points to those RCA jacks as the first check. Otherwise you might end up chasing ghosts for a while.... :)

I didn't say "voluntarily", did I? :D Of course it's not voluntary. But it's a lot easier to snag them in an unsuspecting moment if they are used to the carrier being around the main living area than it is if they flee at the first sight of the carrier.

I really don't understand the need for an 'external' relay with the L-4B. The relay in the amp operates at 30 VDC, and
about 60 mA, and is diode suppressed. Most any relay I've ever seen could handle that easily, and even a 2N3904
transistor would handle that as well.

It certainly won't hurt anything, BUT, is just one more thing to fail. Every radio I've seen specifies the capability
of their internal relay, and as long as it's above 30 VDC and 60 mA I wouldn't worry about it. I keyed my L-4B for
years with a TS-940 in PACTOR!!!

To answer your direct question, 'probably', the T-4XC relay has contacts rated at 2A, but MINIMUM recommended is 12 VDC
and 100 mA. I suppose this is related to corrosion of the 'fine silver' contacts. The 'relay savers' seem to pride
themselves on 5V, uA currents, which results in the 'not enough voltage and/or current' to break through even the
tiniest oxidation. (See TR-7!!)

For maximum reliability, especially if not in regular use, you'd do better with an R10-E1Z4-V185 (fine silver,
bifurcated, 1 mA minimum), or even R10-E1P4-V185 (gold plated silver, bifurcated, (dry circuit [~0 mA] - 1 mA minimum)!

18871. R4B PTO freq way off

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-23 21:31:16 UTC
From: <tharlam@...>
Topic: 18871 Message: 18871

Hello All,

I have an R4B that was given to me. It seems to be working OK except that the PTO frequency is way off.

With the aluminum cover in place, the PTO freq. is about 190 kHz too high (its minimum freq is 5145 kHz, not the 4955 which it should be according to the manual).
The mechanical stop for the slug seems to be OK as the slug slider gets to about 1mm from the front panel stop when the dial gets to its max rotation.
I cleaned the slider and spring contact surfaces, which did not change the frequency.

I removed the aluminum PTO cover and found that the min. PTO freq. then dropped to 5004.
(I would have thought that having the alum. cover around the coil would lower the freq, not raise it, but I guess that shows how little I know.)
I poked on all the components on the PTO board that I could reach, which only caused the freq. to wiggle 100 Hz or so, no big change.

Would any one have an idea on what might be wrong with the PTO?

The freq. with the cover off, while still too high for proper dial calibration, would allow operation over most of the ham band. Is there any reason not to leave it that way until I can find a proper fix?

Thanks and 73,
Rod, VE7VV

Quite by accident I found out that the four-pin inline flyback connector on many older CRT monitor boards has two pins that are almost exactly the correct spacing. Of course, you need to have easy access to scrap monitor boards to find one. I got lucky, as they aren't as easy to find these days as they used to be.

Leon -

Must have missed your post... Yep, there seems to be a rash of those lately. Hope it's not an 'end of life'
situation!! :-)

Best chance aside from a donor unit is the Bogen T725. You need to select the right lead, I'm going from memory here,
but I 'think' it's the Green lead to the Plate of V17, and the _BLACK_ lead to the Plate supply. The Pink leads are the
speaker leads. Just remember you're interested in 'impedance', not turns ratio. The Plate load is 2500 to 4 ohms to
match the Drake speakers.

Available from just about any supplier, including Amazon!! :-)

Or you can just purchase a length of 3/32 brass thin wall tubing from your local hobby shop. Hobby Lobby and most of
the 'craft' stores have about 18" lengths for a buck or two...

Rod, it sounds as if either a capacitor is open, or there's a cold solder joint to one of the caps. There are one or two very small value caps that are mounted off the board (flying leads). Check that these are soldered on each end.

Subject: [DrakeRadio] R4B PTO freq way off

Hello All,

I have an R4B that was given to me. It seems to be working OK except that the PTO frequency is way off.

With the aluminum cover in place, the PTO freq. is about 190 kHz too high (its minimum freq is 5145 kHz, not the 4955 which it should be according to the manual).
The mechanical stop for the slug seems to be OK as the slug slider gets to about 1mm from the front panel stop when the dial gets to its max rotation.
I cleaned the slider and spring contact surfaces, which did not change the frequency.

I removed the aluminum PTO cover and found that the min. PTO freq. then dropped to 5004.
(I would have thought that having the alum. cover around the coil would lower the freq, not raise it, but I guess that shows how little I know.)
I poked on all the components on the PTO board that I could reach, which only caused the freq. to wiggle 100 Hz or so, no big change.

Would any one have an idea on what might be wrong with the PTO?

The freq. with the cover off, while still too high for proper dial calibration, would allow operation over most of the ham band. Is there any reason not to leave it that way until I can find a proper fix?

Thanks and 73,
Rod, VE7VV

The drive screw follower shouldn't be that close to the front.

What is the frequency at the other end?? Should cover 5.455 to 4.955 MHz with room left on the drive screw. If it's
shifted, (well away from the rear end of the drive screw at 5.455 MHz, you may have a bad cap. Very unusual though, so
be sure and eliminate everything else before subbing caps, as that would surely affect the tempco and/or tracking.
Proceed cautiously!!

There isn't any problem running it without the cover, aside from sensitivity to external coupling.

Steve, I've gone through the manual a few times just now and for the life of me, I can't find a section where it mentions the "9 3/4" anywhere. It is comforting that you say the RF Tune should be near 10 but not 10. I've never been much of a 10 meter guy but today my 20 and 15 meter band were just pitiful!

Marco VE2MRN

On Sunday, February 23, 2014 4:42:12 PM, Steve Wedge <w1es1982@...> wrote:

The tuning for the 10m band is done with one set of coil
adjustments, for all three segments. In the manual, they have you peak the
coil at 29.7 MHz or thereabouts, with the RF TUNE on "9 3/4" - I.e., almost to
10. Presumably, this allows the single adjustment to work over the entire
band. It may also have something to do with spectral purity, so
I'll wait for Garey to chime in on this. I have had better results
tuning it a couple hundred kHz lower.

If you're peaking on "10" on all segments, there's
something wrong with the 10m tuning. Someone before you may have been in
there with a "golden screwdriver" or they were running it on 11m. Try
doing the adjustments for 10m per the manual first.

Subject: [DrakeRadio] TR-4 and 10 meter trouble

Hello
folks,

the radio is fine except for 10 meters. No matter which of the 3
positions I set the band on, the RF Tune needs to be all the way clockwise (#10)
in order to here white noise. It seems to drift a little too.. again only on 10
meters. Is there anything I can do/check to fix this?

Marco

Marco -

I'd guess the BAND oscillator is not running on the 10M crystals. Could be an open L2, 3, or 4. Check the oscillator
with a High Impedance Meter on 'TP' on top of the chassis just under the S-Meter. Should read several negative volts on
all three 10M BAND switch positions and on 40M.

Thanks Steve and Gary.

I just checked the PTO situation.

Full CCW rotation of dial
Dial goes beyond .500 (top)/1.00 (bot) to <>
Slug extends about 5/8 inch out of back of coil
Freq is 5004 Hz

Full CW rotation of dial
Dial stops at 0 (top)/.500 (bot)
Slug extends about 1/16 inch out of back of coil, front slug carrier about 1/16 inch from front panel
Freq is 5542 Hz

What does that suggest?

Rod

That should only tune at "9 3/4" at the top end of the 29.1 scale. The other segments should tune somewhere nearer the middle.

As Garey mentioned, there may be a bad inductor. If you don't know the person you got it from, don't discount that it's possible that it was tuned for 11m...

I bought the Drake 11 years ago from a ham in Ontario. Like I said, 10 meter hasn't been my band so I never really pushed the issue.
When I do the alignment and get to step "C" Crystal Oscillator Alignment, I am getting -0.27 to -0.31V on the three 10 meter positions and about -0.34V on 40 meters. Signals are coming in strong but not having the play on the RF Tune is worrisome. Garey, I don't see L3 nor L4 in the manual diagrams. I really should get someone who knows what he's doing to look at this issue. Thanks for your time. I appreciate it.

Garey, and the group,

My L4 key line sits at 39 volts. And measured key current is almost 100 ma.
Not a deal breaker and your mileage may vary.

I guess the big problem is using an amp like this without an interface with
the newer radios. A SMT transistor will lose that battle.

I've would never use a interface between a old Drake, or heathkit rig,
those guys use a multi-contact relay that would more than handle the
current and voltage.

and a FYI,

I found that a MOLEX .062 PIN fits the relay socket on the L4 perfectly.
So, a hunk of wire, some heat shrink tubing and you've got a cable. Not
pretty, but certainly workable.

There is one adjustable coil and it is connected to the upper 10 meter switch position. Then there is a small semi loop wire going from this switch position to the middle 10 meter switch position. Then there is a small semi looped wire going from the middle 10 meter switch position to the lower 10 meter switch position. So you are adjusting the coil to the top of the 10 meter band with the adjustable coil and then as you go lower in the band by switching the band position switch you are adding a little bit of inductance by adding a little wire each time you lower the band switch on the 10 meter band.

Subject: [DrakeRadio] TR-4 and 10 meter trouble

Hello folks,

the radio is fine except for 10 meters. No matter which of the 3 positions I set the band on, the RF Tune needs to be all the way clockwise (#10) in order to here white noise. It seems to drift a little too.. again only on 10 meters. Is there anything I can do/check to fix this?

Marco

That pretty much rules out 11m hanky-panky. Check for cold solder joints before taking parts out.

Subject: Re: [DrakeRadio] TR-4 and 10 meter trouble

There is one adjustable coil and it is connected to the upper 10 meter switch position. Then there is a small semi loop wire going from this switch position to the middle 10 meter switch position. Then there is a small semi looped wire going from the middle 10 meter switch position to the lower 10 meter switch position. So you are adjusting the coil to the top of the 10 meter band with the adjustable coil and then as you go lower in the band by switching the band position switch you are adding a little bit of inductance by adding a little wire each time you lower the band switch on the 10 meter band.

Lee, w0vt

I bought the Drake 11 years ago from a ham in Ontario. Like I said, 10 meter hasn't been my band so I never really pushed the issue.
When I do the alignment and get to step "C" Crystal Oscillator Alignment, I am getting -0.27 to -0.31V on the three 10 meter positions and about -0.34V on 40 meters. Signals are coming in strong but not having the play on the RF Tune is worrisome. Garey, I don't see L3 nor L4 in the manual diagrams. I really should get someone who knows what he's doing to look at this issue. Thanks for your time. I appreciate it.

Steve, I've gone through the manual a few times just now and for the life of me, I can't find a section where it mentions the "9 3/4" anywhere. It is comforting that you say the RF Tune should be near 10 but not 10. I've never been much of a 10 meter guy but today my 20 and 15 meter band were just pitiful!

Marco VE2MRN

On Sunday, February 23, 2014 4:42:12 PM, Steve Wedge <w1es1982@....com> wrote:

The tuning for the 10m band is done with one set of coil adjustments, for all three segments. In the manual, they have you peak the coil at 29.7 MHz or thereabouts, with the RF TUNE on "9 3/4" - I.e., almost to 10. Presumably, this allows the single adjustment to work over the entire band. It may also have something to do with spectral purity, so I'll wait for Garey to chime in on this. I have had better results tuning it a couple hundred kHz lower.

If you're peaking on "10" on all segments, there's something wrong with the 10m tuning. Someone before you may have been in there with a "golden screwdriver" or they were running it on 11m. Try doing the adjustments for 10m per the manual first.

Bob -

OK. It's NOT V10. Sounds like the V9a audio oscillator ain't!!

The ~ 1kHz audio note generated here is 'keyed' by CR15, and amplified by V9b. Output to the BAL MOD for TUNE operation
is from the Cathode of V9b, and the SIDETONE comes from the Plate of V9b.

A shorted CR15 would give the symptoms you describe, as it would prevent the audio signal, IF it's there, from reaching
V9b. The V9a oscillation is controlled by switching in a phase shift network, R97, 98 and

99 along with associated
capacitors. Here the most likely problem is dirty switch contacts on the FUNCTION switch, on the front side of the
fourth wafer from the panel.

The signals out of V9b are MISSING, either because V9a is not generating them, or they're being prevented from reaching
V9b, most likely by a shorted CR15.

I certainly agree on the value of Gareys CD's.

I have both the C-line and TR4 series and they have saved me several times over the years from having to send my gear out for repair.

Plus Garey is just a treasure when it comes to Drake equipment.

I've had 4 C-lines of the past 40 years....never could understand why I sold the first three sets....but I'm keeping the fourth (grin).

Recently picked up a very nice TR4CW/RIT that is also a keeper.

I don't know why I keep all of this tube stuff...I have Elecraft K3 and KX3 rigs...solid state and simply outstanding equipment...but I cut my teeth on tube stuff 57 years ago or so and just can't shake them (grin).

I sent a note to Garey earlier about replacing 6JB6's with 6GJ5's....the 6GJ5's work FB and neutralize easily...just make sure to get the "short" version of the 6GJ5...evidently they also make a "tall" version that won't fit properly in the T4XC final cage.....don't ask me how I know!!

Bill,

That 2 pin connector can be obtained used, occasionally, on Upay (Ebay). They run in the $19-40 range for one. It is more cost effective to do the conversion to the RCA phono jack to ensure shielding as well as avoiding polarity problems.

Subject: [DrakeRadio] L4B Relay Connector

I need a couple of the two pronged relay connectors; one for the AC4 and one for the L4B. I also need 4 of the rubber covered screws used on the MS4 that hold the AC4 inside. I know I could anything but at this point I have spent good money having the C-Line refurbished and have rebuilt the AC4 and power supply for the L4B I might as well make everything right. I have found the rubber covered screws at one vendor but am just trying to get everything from one source. Just let me know off line. No need to clog the reflector with this info.

I am anxiously looking forward to getting this stuff on the air.

18894. 7-Line paint

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-24 02:36:10 UTC
From: L L bahr
Topic: 18857 Message: 18894

I went to a swap meet yesterday and picked up a Drake WH7 wattmeter. Everything about the meter is great, except someone painted the cabinet with High Gloss Black paint. I'd like to repaint it close to it's original color. Does anyone on here have the color specs for the 7-Line paint color? I guess if all else fails I can try and color match the paint at Sherwin-Williams by taking a piece of 7 line equipment down to them to try and match. If my eyes serve me correctly , the paint is a very dark gray getting close to black.

Anyone have any ideas on this? I've done plenty of 4-line painting but never on a 7-line piece of equipment.

Lee,
You almost have to just "match what you have" that you like the best. I have seen the old original black sticky paint turn to all sorts of shades of gray and almost to a white before repainted. Then Drake went to what I call a nice charcoal gray color, then the last new cabinets were actually Black, like the R8 series stuff (likely because the new vendors were making black). I think I'll have the local auto paint guy match the best looking one I have and paint all mine just to match and let it go at that!!!!!! Just an idea.

Hi Don,
Thanks for the ideas. I bought a TR-7 station new when they first came out, and all my cabinets in that line got "sticky " over time. (The paint had a flock type soft feel to it when it was new.) Sometime latter, Drake sold me all new cabinets with that dark Smokey gray paint on them to fix the problem. That's the way they are today.

This newly acquired WH7 has a terrible gloss black paint job on it and it will look much better with a Satin paint finish. Except for the paint job, the meter looks and works like it was new. I could not pass it up for $25.00. Most likely I'll take my other nice WH7 down to Sherwin- Williams to match the paint for me.

I certainly agree on the value of Gareys CD's.

I have both the C-line and TR4 series and they have saved me several times over the years from having to send my gear out for repair.

Plus Garey is just a treasure when it comes to Drake equipment.

I've had 4 C-lines of the past 40 years....never could understand why I sold the first three sets....but I'm keeping the fourth (grin).

Recently picked up a very nice TR4CW/RIT that is also a keeper.

I don't know why I keep all of this tube stuff...I have Elecraft K3 and KX3 rigs...solid state and simply outstanding equipment...but I cut my teeth on tube stuff 57 years ago or so and just can't shake them (grin).

I sent a note to Garey earlier about replacing 6JB6's with 6GJ5's....the 6GJ5's work FB and neutralize easily...just make sure to get the "short" version of the 6GJ5...evidently they also make a "tall" version that won't fit properly in the T4XC final cage.....don't ask me how I know!!

Hi Rod,

Any & all frequency checks with the Drake PTOs MUST be made with that aluminum can cover IN PLACE...

I have found that with my T-4X, the frequency difference is almost EXACTLY 100-KHz higher with the can off, vs. having the can on...

That's been my personal experience here, FWIW.

The other pins on the one I had were of a different spacing. I suppose to prevent the yoke from being plugged in wrong. Not all monitors used this connector either, but it was somewhat of a quasi-standard for a little while.

I miss the days when you could swap the yoke connectors on the old IBM mono monitors and flip the screen or reverse it. Great fun!

The early 7 line cabinets were painted with a gray paint that was supposed 'heal' when scratched. They did not know at the time that after a couple of years the paint would degrade into the sticky mess that it turned out to be.
The later Cabinets were not painted, the were vinyl clad dark gray.
Sometime in around the 90s the demand for replacement cabinets was great enough that Drake made some however the only material that they had on hand was black vinyl clad.
The black cabinets were only on replacement parts, they never used on original radios.

The W-4 and MN-2000 meters used the 1N295 which according to my notes from my MN-2000 repair from eons ago the 1N34 was a good replacement according to Drake when I called them in 1989! I'd guess that although the circuits are a little different between the 4 and 7-line units that the diodes were most likely the same.

Hi Carl,

Thanks for your response. Yep, the MN-2000 uses 1N295's.

I see a couple of sites have a few 1N295's available. An old QRZ.com thread about diode replacement options to resuscitate a dead MN2000 stated the NTE 109 was the 1N295 replacement or you could "substitute with a 1N34A or 1N270 germanium - which are used in detection circuits of many RF/SWR Meters." Any comments about these replacement suggestions?

It is also interesting to compare the MN-2000 wattmeter components / circuitry to that of the MN-7. Basically the same as one might expect but with some little component value tweaks here and there.

Hmmmm.

Thanks agn,

73

Chris -

The originals were AA119 diodes. These are Germanium diodes, 30V PIV and 10 mA.

They are available, but take a little looking. I think Newark had them the last time I looked, ~$2 each.

Other choices would be the 1N295, used in the W-4; the 1N270 generally available; The 1N277 ?; NTE109.

Second choice would be a Schottky like HP2800, 1N5711, etc. These would work fine, but might be slightly different in
the non-linear part of the scale, very low powers.

18912. Re: Drake Paint

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-24 18:14:42 UTC
From: L L bahr
Topic: 18912 Message: 18912

Hi Lee, Yes I have painted 4-line cabinets. I am not a professional painter, but have had great results. First off there were two types painted by Drake. for 4-lines. The plain Satin Black type and the "spattered" black type. Most of my repaint jobs needed to have the "spattered" type look to them. That is, a Satin base coat and then "spattered" with a light Gloss Black paint. If you want a really nice professional look to your base coat and want to do it yourself, don't use hardware store spray can paint. It always shows "hot spot's. At least for me that is the case. I buy some automotive Black Satin auto paint from an automotive paint store and then put it into a PREVAL throw away paint bottle driven by a PREVAL compressed air throw away canister. This really gives you a great Satin paint job. (Lacquer is the best. Much better then the $5.00 spray paint cans.) The PREVAL bottle and air canisters can be purchased at The Home Depot and many other places. Using the PREVAL system never gives me "hot spots". Then to apply the black gloss paint I take a $5.00 can of High Gloss paint and enlarge the nozzle hole so the paint "spatters" out of the can rather then come out a fine spray. You need to practice what distance you need to use to give you the correct size gloss droplets. Once done, you will be hard pressed to see a difference from a Drake original. The PREVAL system and automotive paint base coat separates an OK job from an outstanding repaint job. If you have an early 4-line, I'd suspect all you need is a Satin Base coat on your cabinet. Hope this helps.
Lee, w0vt

Hi Lee...

"I don't know anything about 7-line painting, but would appreciate any guidance you might have on the 4-line grays. I've got a box I'd like to paint to match my R-4 and hints would be appreciated. Especially something easy like Krylon in a can!"

18913. T-4X gears skipping?

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-24 19:19:02 UTC
From: Steve Wedge
Topic: 18913 Message: 18913

Got this T-4X on the bench. It was working prior to my partially disassembling it and cleaning. The beveled gears the feed the shaft over to the band oscillator and premixer may have skipped a tooth. I had to unbend the detent and had removed it, then replaced it. Now, all I can get this transmitter to do is show idle current. The switch contact on the band oscillator seems to lose its centering when it gets up to the 10m end.

I can't get those gears to skip a tooth by holding one and turning the shaft, but this seems definitely odd.

Anyone ever had to deal with this?

73,

Steve Wedge, W1ES/4

Steve -

Not specifically, but perhaps someone has been 'fixing' it!

The right angle drive combo limited by the BAND switch detent has a fairly limited range for error.

Make sure the BAND switch shaft hasn't been put back 180 degrees out.!

Hello all,
For any of you that might be in the market for a Drake R7A
www.randl.com (http://www.randl.com)
has one, looks clean enough and they have checked it out.

Right now on Ebay they have the accessories for a TR7, in that the speech processor, W7 watt meter, and the adapter harness cable for attaching to an R7A .
CR.. I don't have that kind of $ available Carl wd8nhk

The detent on the back was 180 out. The alignment is still not perfect. Carrier oscillator seems to have some modulation on it and only oscillates when rig is in xmit (which, IIRC, is normal).

Rig still not transmitting so there's something else wrong. Can't get the band osc to work on 10 at all.

18924. Re: [DrakeRadio] R4B PTO freq way off

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-25 03:24:36 UTC
From: <tharlam@...>
Topic: 18871 Message: 18924

Hello Garey and others,
Here is more info. I hope you this will give you more to go on for helping me.
(Note, all freq.'s below are with the alum. cover in place.)

Before changing anything here is what the PTO was showing.
Full CCW dial rotation, dial stops at <> (beyond the .500 (top)/1.000(bot) marking.
Freq. 5145 Hz. This was the minimum available PTO freq.
The manual says the minimum freq. for the 500 Hz tuning range should be 4955, but I believe that at the <> point is should be even lower, maybe 4900. (The PTO is marked 4.9 to 5.5.)
Thus the freq. is at least 190 Hz too high, maybe 245 Hz too high.

After adding an extra 10 pf of capacitance to the PTO (added across the coil):
Full CCW dial rotation, dial stops at <> (beyond the .500 (top)/1.000(bot) marking.
Freq. 4919 Hz. This is the minimum available PTO freq.
Dial at .500(top)/1.000(bot) marking.
Freq. 4978 Hz.
Full CW dial rotation, dial stops at 0.000(top)/.500(bot) marking.
Freq. 5408 Hz.
The minimum freq. is now close to what it should be, but total tuning range is only 489 Hz, not 500 or 600 Hz, so something is still wrong.

The problem may be mechanical rather than electrical.
The slug slider appears to move as far in both directions as is mechanically possible.
However, I see that the slug screw has quite a bit of thread showing when the slider is at the maximum insertion point, suggesting to me that the slug might actually be able to go further into the coil to produce a lower freq.
I have uploaded two photos showing the current max./min. travel of the slider, see:
http://members.shaw.ca/drrg/temp/ http://members.shaw.ca/drrg/temp/
If the slug rod is out of position on the slider control, how does one fix that?

Thanks for any and all advice.

Rod, VE7VV

Rod -

OK, the photo shows what I thought might be the problem. The travel is displaced WAY toward the front. If you look
down on the right side of the gears in front of the gearbox, you'll see a spring loaded pin that makes the mechanical
stop by extending into a detent on the back of the gear. If you push that pin back in long enough to get the roll pin
extending from another gear to get past and allow you to make another full turn. Based on how far forward the follower
is, you may have to go past the stop twice.

It takes some fiddling, and you'll be able to see what it's doing easier than I can explain it by typing!! You should
have 20 turns of the MAIN tuning knob, and exactly 500 kHz spread, with the frequencies at 4.955 and 5.455, plus (or
minus) another 25 kHz past those end points. The follower should travel close to the full length of the drive screw.

18926. Re: [DrakeRadio] R4B PTO freq way off

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-25 04:22:49 UTC
From: Richard Knoppow
Topic: 18871 Message: 18926

Check the stop but also check the dial. The dial is
on a friction hub and can be slipped with your fingers.
There is a stop which is part of the gear mechanism. If the
gear has slipped the frequency can be way off but it will be
off in the same direction on both ends (i.e., too high or
too low). Take your extra cap off and check the stop and
dial position. Note that the shield can _must_ be in place
for the range to be correct.
The stop works by means of a pin which is moved by a
cam. If the lubrication has dried out it may not work
properly allowing the drive gear to go too far.

18927. TR-4C S-meter saga continues!

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-25 08:43:27 UTC
From: k7mks@...
Topic: 18927 Message: 18927

On 40m receive in LSB S meter reads steady at 0 as C-130 is turned. On USB S meter moves between 0 - 1.5 or so when C-130 turned

The opposite is true on 20m - steady S meter on USB .S-meter movement from 0 - 1.5 or so on LSB w/ C-130 turning.

C-130 had been adjusted for equal white noise on either sideband.

Same test run on my TR4-CW/RIT shows no S-meter movement off 0 in LSB and USB when C-130 turned.

Garey K4OAH emailed a procedure for filter evaluation - both filters appear within specs.

And the search for the gremlin continues

Thanks joe k7mks

18928. Re: [DrakeRadio] T-4X gears skipping?

Will have to try subbing. It was working fine before I refurbed it. Have never had one fail before after this, but there's always a first time. It was working marginally when I first fired it up (It keyed okay and didn't smoke - no idle current, due to totally dead finals). Had it going over 100W on all bands before taking it apart. The rear bandswitch detent was bent, rendering the bandswitch detents mushy-to-nonexistent. I removed the detent assembly and straightened it, reinstalled it where I thought it should go and, of course, it was 180 out. I do believe it's in correctly now.

Got a lot of real estate stuff to do today, so this will have to wait. The rig looks marvelous, so it's worth continuing.

Hi Guys,

New to the Drake fold :) - I'm used to restoring and repairing Heathkit, Swan and Ten Tec mostly (as well as the modern radio's including - takes deep breath - surface mount !!!)

I've often admired Drake gear and love to bring - shall we say 'older' radio's (yes including valves!) back to life. I also repair for others when they have 'given up'.

Now to my new acquisition, just got a TR5 (still to be picked up so don't know what condition its in really) and would like to know any 'common' issues with it (are there any) I know not too many were made so perhaps not many survived this long. It also comes with a PS75,

I've a manual - easy find on the web :) - but does anyone have a schematic that they would be prepared to let me have - pdf or scan would be very helpful.

Anyway I plan a full review and restoration so look forward to sharing some pics with anyone that's interested!

thanks
Chris

18933. R-4C loss of audio output following Sherwood Power Supply and Audio board upgrade

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-25 18:18:02 UTC
From: <dcoffman@...>
Topic: 18933 Message: 18933

I have upgraded a recently purchased R-4C with the Sherwood power supply, audio board and Hayseed Ham's caps. Prior to the upgrade, the unit worked as it should, following the upgrade, I have lost the audio output. When attached to an antenna, the S-meter bounces bank and forth with received signals, so I'm comfortable that the receiver is working properly however; there is no audio output. I have traced the wiring on both boards a number of times to ensure that I did not lose power to any components. I placed my Oscilloscope on the wiper of the AF gain pot and do not see a signal. I was wondering if anyone else had had this issue when upgrading the components or may have a suggestion for a troubleshooting starting point.

I have a local elmer that frequents this group quite often that will find it quickly however; I was trying to avoid troubling him with the issue and try to find it while its on my bench. I'm sure its a simple issue but I am not talented enough to find it.

Regards,

Doug - N9XTF

Doug -

Serves you right!!! Some people never learn.... :-)

You didn't mention the 3rd IF replacement or the Product Detector replacement.

My guess is the input or output of the Audio Board. You'll probably find a missed, broken or damaged connection. With
the AF GAIN control set above 50%, touch your finger to the center terminal. You should get a hum or buzz from the
speaker. If not, the problem is 'past' the AF GAIN control. If you do get the buzz, it's earlier in the radio.

18935. TR-4C S meter zero

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-25 18:57:37 UTC
From: k7mks@...
Topic: 18935 Message: 18935

I'd appreciate a quick email indicating,. from those who have a TR-4C in good working condition, if your S-meter correctly "zeros" on both UPPER and LOWER sideband. This is with no signal input and the receiver "white noise" is similar in sound in both UPPER and LOWER.

The reason for this request is that I have heard that the some TR-4C's have a tendency to have unequal S-meter readings when zeroed
on one sideband.

Thank you,

Joe K7MKS

18936. TR-7 S-Meter readings with narrow SSB filter

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-25 19:03:24 UTC
From: Allen Jones
Topic: 18936 Message: 18936

I have much higher S-Meter readings on my TR-7 when using the 1.8 KHz filter, very noticeable with weak signals. S2 reading on the stock SSB filter increase to S4-5 using the narrow filter as well as an increase in background noise.

I checked the sensitivity with my Wavetek generator and get a S-9 reading with 50uv in on 14.3 Mhz. When I use the narrow filter the reading increases to 10db over S-9. I also see a noticeable difference in the MDS.

Wonder if anyone else has experienced this or do I start looking for a problem?

Thanks

Allen, W9DZ

I'm still having trouble deciphering what you are talking about.

When you did the filter bandwidth check by listening to the Calibrator as I described earlier, were the two 'tops' at
about the same S-Meter reading??

I can see that 'background' noise can be different on different sidebands. This is usually a result of differences in
bandwidth of the two filters, and any 'pre-filters' Per my previous, you say that both filters are showing correct (~
2.5 kHz) bandwidths. Extreme excursions of the CAR OSC (C130) can vary the 'noise power' in each filter by moving it to
the edge of the IF transformer tuning. Think of the IF transformer passband as a filter. Changing C130 'moves' the two
crystal filter passbands around that IF passband. IF a passband is moved too far, the noise could decrease in one
sideband by being outside the transformer passband, or at least down on it's skirt.

Can you set C130 for 9.000 MHz using either a counter or by listening on a general coverage receiver?? It really
shouldn't be very far (+/- 100-200 Hz?) from that.

Sounds like a problem with the standard filter or it's switching diodes. Does the passband 'look' about the same on
both? Tuning across the Calibrator.

Topic: 18933 Message: 18939

Gary,

Yes I'm a big bull in a china shop; my father has given me grief for this since I was a kid.

I did the power supply board because both R-4c receivers that I have recently acquired have dis colored traces, repaired traces and parts replaced. I did the audio board because the audio output seemed to require the AF again to be turned up quite far for a s3 to s5 signal to be heard at a comfortable level. That coupled with the heat generated by the output transistor. For general info, both receivers are later serial numbers with 6Ej7 tubes. The other R4C remains unchanged until I see how this one works out.

After conferring with my Elmer, the product detector or the 3rd mixer change didn't seem applicable to me. I haven't noticed any issue with the third mixer but I may be missing something too.

I placed my finger on the wiper with the AF GAIN at 50% and ranges higher and got nothing from the speaker.

Doug -

OK. Then the problem is AFTER the wiper of the AF GAIN control. This probably connects to the input of the Audio
board, either via wire or possibly a coupling capacitor. This connection is the first suspect. IF this is good, the
next would be the OUTPUT connections to the audio board. These go to the PHONES jack and SPEAKER jack. I'm going to
suggest the connection to the PHONES jack, as this is a 'shorting' type that interrupts the SPEAKER circuit when phones
are plugged into it. It has three terminals rather than the typical two of a 'plain' jack. Connecting the Audio board
output to the wrong terminal is a possibility. IF this is correct, then the Audio board isn't working. Does it have
the proper B+ applied?? B+ on the board where it should be??

Richard, Garey -Thanks! That was just the info I needed - it's fixed! Great Group!

You were correct, it was a mechanical problem. It took me a while to figure out just how the dial/gear mechanism works. Your explanations were bang on, but I didn’t get it all straight for a while.

The problem was that, first, the spring loaded pin that falls into the dial gear detent was not doing that. The whole thing was way out of step. Once I corrected that by holding the pin back and rotating the dial so the pin would fall in properly (thanks Garey), the freq was now way off in the other direction. Once I figured out how to separately turn the dial and slug (thanks Richard), I could easily get the PTO freq back to the right place. It was all very simple and quick once I knew what to do.

Reminds me of the old joke about the retired steam engineer called in when the steam engine stopped working. He picked up a hammer and gave it a whack and fixed it, then gave a bill for $10,000. The owner said "$10,000 for one whack"? The engineer said, "No, $1 for the whack, $9999 for knowing where to hit it".

Rod -

Richard suggested moving the dial by slipping it on the hub. If you have to go very far, there is a much easier way.
Looking down on top of the gearbox, you'll see that the leftmost nylon gear shaft is pulled toward the hub by a spring.
You may also notice that the hole in the front wall of the gearbox for this shaft is oblong! If you pull out (away from
the hub) on that shaft, the nylon gear is disengaged and you can spin the dial wherever you want it!

Here, you just need your own hammer. We tell you where to hit it at no charge!! :-)

Hello Chris and group,

I understand you have the schematics already from Garey. If not, I have an original one here and would be prepared to make a high quality scan. BTW, does anyone know why there is none on the web? Any intellectual property issues? Or just the fact that it is a bit awkward to make a good scan out of it...

My TR5 had a little bit of trouble with scratchy switches and pots. Especially the speaker and cw filter switches were annoying because I use them often. A bit of Deoxit did the job.

Apart from that no issues here and nothing known to be common. But that is probably because there are so few in the wild...

It is not so easy to service the TR5 because there are just the schematics but no additional information like placement plan or more help to find out where the component sits. If one could just get hold of the Drake documentation...

The TR5 is not nearly as good as the TR7 but it is a nice radio that I would not want to miss on my bench. And you have to get used to the PTO behaviour. You have to turn in the other direction... ;-)

Good luck!

Hello Gary,
Yes, I would say that the response sounds OK as I tune across the signal using either filter. But, I also see a difference there as the calibrator signal is 10db stronger when using the narrow filter.

Definitely an issue, I would say. 10 dB difference is way too much. The signal should be even slightly stronger on the wide filter.
As Garey suggested, check the pin diodes on the filter board. If you are unlucky, your 2.3 kHz filter is bad.

What a difference a day makes.

Got home, fired up the T-4X and started probing more methodically. Signals off V1 and voltage levels were a bit off.

Jiggled the BAL MOD pot, and - surprise! - was able to get some plate current and signal.

Must have been some crud that got on the wiper arm.

Rig still needs a full re-do of the alignment. I think the dirt on the neut cap actually had some capacitance, as the neut seems to be off, and I'm only getting about 30W out, but it's a start.

BTW, checked the alignment of the band osc and pre-mixer switch wafers against another T-4X and they were pretty much spot-on. Band switch still feels mushy, so I may swap it with another, less-nice rig.

Subject: [DrakeRadio] TR-7 S-Meter readings with narrow SSB filter

I have much higher S-Meter readings on my TR-7 when using the 1.8 KHz filter, very noticeable with weak signals. S2 reading on the stock SSB filter increase to S4-5 using the narrow filter as well as an increase in background noise.

I checked the sensitivity with my Wavetek generator and get a S-9 reading with 50uv in on 14.3 Mhz. When I use the narrow filter the reading increases to 10db over S-9. I also see a noticeable difference in the MDS.

Wonder if anyone else has experienced this or do I start looking for a problem?

Thanks

Allen, W9DZ

I just did some additional checking. The 10db difference also exists when comparing signal strength using the AM and CW filter.
No problem transmitting so I'm guessing the filter is OK as it is used for all modes according to the service manual. Easy 100+ watts out with the mic gain at 9 o'clock.

How does one go about testing the PIN diodes?

Garey: Thanks for a valuable tutorial on filters etc. I'm beginning to feel that the 9.000KHz crystal has moved slightly and may be repl aced. My other TR4-CW/RIT has a 9 MHz filter that is right spot on Will keep you posted

Subject: Re: [DrakeRadio] TR-4C S meter zero

I'm still having trouble deciphering what you are talking about.

When you did the filter bandwidth check by listening to the Calibrator as I described earlier, were the two 'tops' at
about the same S-Meter reading??   NOTE Tops were within 1/2 S unit or so
.

I can see that 'background' noise can be different on different sidebands. This is usually a result of differences in
bandwidth of the two filters, and any 'pre-filters' Per my previous, you say that both filters are showing correct (~
2.5 kHz) bandwidths. Extreme excursions of the CAR OSC (C130) can vary the 'noise power' in each filter by moving it to
the edge of the IF transformer tuning. Think of the IF transformer passband as a filter. Changing C130 'moves' the two
crystal filter passbands around that IF passband. IF a passband is moved too far, the noise could decrease in one
sideband by being outside the transformer passband, or at least down on it's skirt.

Can you set C130 for 9.000 MHz using either a counter or by listening on a general coverage receiver?? It really
shouldn't be very far (+/- 100-200 Hz?) from that.   NOTE C-130 set
 at the highest, to 899.8985

Perhaps we're coming from the wrong direction... Maybe the narrow filter is shorted? Does this filter show the proper
bandwidth when tuned across the Calibrator signal??

The diodes can be checked in the usual fashion, best is the 'Diode Test' function on a good DMM, usually indicated by a
diode symbol on the range switch.

There are four diodes associated with each filter one Series and one Shunt on each end. The Series diode should be
conducting and the Shunt diode reverse biased on both ends of the filter selected. This is reversed when a filter is
NOT selected. Probably wouldn't hurt to check the -5V supply too. It is typically -3.5 V or so.

I think you said you didn't have extender cards, so the best that you'll be able to do is the ohmmeter check with the
board pulled out. If you had extenders you could check the voltage on each end of each diode and tell if they were 'on'
or 'off'.

OK.... That's slightly low, obviously, so maybe you can't get close enough to one filter. With it turned all the way
up, you probably still have 'hissy' audio on that sideband.

Just to be careful, check the relay K2 contacts. Back corner near the CAR OSC. The relay should be de-energized in
SSB, and the NC closed contacts short out a 68 pF cap in series with the crystal to ground. If that ground (contacts)
isn't good I would expect the frequency to be higher, not lower.

You may just be fighting crystal aging.

I think I may have found something.

If C105 was open or showed 5 Meg resistance across it, would that stop the side tone going through the antivox cable back to V9? Looks like it in the schematic.

The covering of C105 has pulled back, exposing the plates and laying them bare against the circuit board. Never have seen that before. I can send you a photo of it tomorrow.

All other ceramics of .01 value show resistance across in the 40K-50K range. Bob

Geoff:

I am using stock Drake 7077 mics on my TR-5 and TR-7's with good results on all three. They are all hooked through SP-75's which I rarely turn on but if I need a bit of a boost I'll crack the SP-75's open VERY slightly. Mic wiring would appear to be all the same but will admit I have not checked the schematics.

Nice little rig – kinda quirky relative to it's TR-7 big brother – that reversed tuning seems to be the hardest part to get used to. Interesting they added a speaker on/off switch to get around the TR-7's inability to crank down to zero audio.

I was being very stupid this morning. I meant turning
the _dial_ to get it into alignment. Its possible to align
the stop by lifting the small gear but I was thinking of
something else. I know about this problem because I've had
it and had to figure out what was wrong. If the stop pin is
sticky it can allow the tuning gear to over travel. When
everything is set right the VFO is very smooth both
mechanically and electrically.

How are you measuring this resistance? Generally,
ceramic caps have very low leakage, i.e. very high parallel
resistance. They must be measured out of circuit. Cracked
casing on ceramics is a problem and comes from stressing the
leads. There may be damage to the insides. Ceramic caps in
general have very long lives but the life also depends on
the type of dielectric. Hi-K types do age somewhat while
low-K C0G and NP0 types do not or age very slowly. Any type
will long outlast paper caps.

Same story here.... never checked the schematics but the 7077 works
nicely on the TR7 and the TR5. Geoff, are you aware of any difference?

Regarding the speaker switch they followed the R7 scheme. A plugged in
headphones will not mute the speaker. That is what the switch is for.

18963. Filter Options for R4C assistance please

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-26 09:44:31 UTC
From: <chrispickett@...>
Topic: 18963 Message: 18963

Hi Chaps, just got my4 Line back up and running after some issues with the AC4, now fully rebuilt, and I would finally like to get round to installing the filters I have had kicking around for the R4c for a while.

The units I have are as follows:-
INRAD GUF-1 Filter
I also have a pair of filters from Rob Sherwood CF-2K/8LSB and a CF-2K/8USB.
I have no fitting instructions for any of them and wonder if anyone has done these mods that could possibly mail me off list with the info I require.
Any help would be gratefully received as I am sure these will enhance the performance of the receiver by some considerable margin.

On another note, are there any good modifications known to improve the transmit audio of the Drake T4XC. I personally like the sharp narrow 'old school' audio but have a Turner Ceramic Fist mic and also a Hi Z Heil Gold-line but everyone moans about my highly 'nasal audio' - again ideas or suggestions are most welcome.

From: <w5rkl@...>
Topic: 18963 Message: 18964

Chris,

I do not have experience with the Sherwood CF-2K/8LSB/USB filters. I'm not sure but I believe the USB and LSB Sherwood filters you speak of are designed to be used on the Sherwood's filter switch PC board that mounts on the left side of the receiver, just left of the PRESELECTOR tuning assembly. The filters are switch selected by a switch assembly that replaces the AGC switch on the lower right of the receiver's front panel.

I have installed the GUF-1 filter in my R4C which took about 30 minutes to complete.

The INRAD GUF-1 filter is smaller than the Drake factory filter. INRAD provided a mounting drilling template with the GUF-1 filter.

The original filter is located on the top of the chassis. The filter is identified in the R4C manual on page 5-6, Figure 5-1, as the "8Khz B.W. first IF xtal filter".

You will need to drill 2 new holes in the top of the chassis, that's what the drilling template that came with the GUF-1 filter is for. You will be able to reuse one set of holes but you will have to drill the other set of holes.

Drilling the holes is self explanatory, simply remove the old filter, move the filter wiring so the wires will not get damaged during drilling, tape the template onto the top of the chassis, drill the 2 additional holes, clean up any burrs, mount and connect the new GUF-1 filter, and you're done. Check for and remove any metal shavings that may have gotten lodged onto the circuit boards or between tube pins before applying power.

You should check the receiver's alignment and make any necessary adjustments. That's all there is to installing the GUF-1 filter in the R4C receiver.

"Everyone moans about my highly nasal audio"

Who is "everyone"? I doubt "everyone" is every station you talk to, most likely only a few stations.

If your transmit audio is easily understood, is not causing splatter because the MIC gain is set too high, sounds muffled because of microphone impedance mismatch, or is not distorted, then there's absolutely no reason you should make any modifications to the T4XC speech amplifier just to suite a few stations.

I use a Turner desk microphone with my T4XB and a non-amplified D-104 with my T4XC. None of my Drake Transmitter's speech amplifier have been modified. If someone doesn't like how my audio sounds, oh well. I suspect you will get audio reports from many different people, some will say you sound fine, while others will say you need to rip out the speech amp, redesign it, just so you sound just like them! You will not please everyone and modifying the transmitter's speech amp to suit "everyone" is just silly.

Hi Guys, I have both 5 & 7 lines and to be honest about it I like the 5 better than the 7. Mine is more stable, where ever you set it is where it stays, where the 7 will move around a bit, so I use the RV75 most of the time. As for the Mic plug, the 7 & 5 both use pin's 1 or 4, they are connected together. 4 being used for the D104 type mic's.
Take Care

Thanks to everyone for the great suggestions. I finally settled on Gary’s response because in my case
it required getting a good friend involved because he has the tools and workspace I would want
to involve. His help was invaluable and Gary’s suggestion of the tubing and where to get it was
accurate too. I have now manufactured several of these and they work great.

Or you can just purchase a length of 3/32 brass thin wall tubing from your local hobby shop. Hobby Lobby and most of
the 'craft' stores have about 18" lengths for a buck or two...

How are you measuring this resistance? Generally,
ceramic caps have very low leakage, i.e. very high parallel
resistance. They must be measured out of circuit. Cracked
casing on ceramics is a problem and comes from stressing the
leads. There may be damage to the insides. Ceramic caps in
general have very long lives but the life also depends on
the type of dielectric. Hi-K types do age somewhat while
low-K C0G and NP0 types do not or age very slowly. Any type
will long outlast paper caps.

Topic: 18933 Message: 18974

Garey,

When I place my O'scope probe on the hot side of the AF gain control, I do not appear to get an incoming signal. The new amp board modification requires the removal of Q11 output transistor and the removal of the driver Q10. Then new audio board input is connected to the wiper of the AF gain control via RG-174 coax, shield to the other shields on the AF gain pot and a wire added from this terminal on the AF gain to a ground lug just behind it. The amp board's only ground is the braid of the coax. I tore it all back down to ensure that I did not have a short in the coax feeding the amp board or a short in the cable feeding the audio to the AF Gain pot; in which I did not. B+ is picked up off the audio board on the pin that connects the blue wire to the audio xfmr. The amp board uses an LM383 transistor; Pin 5 has 12VDC, Pin 4 has 6VDC, 3 ground, 2 and 1 have less than a half volt. The output of the amp board goes to the phone jack lug that has the bare wire with a shrink tube coming form the secondary of the audio xfmr. I do not have a signal at either the phone jack or the speaker jack. Again, I cannot detect a signal coming into the hot side of the AF Gain Pot. I see signal on the secondary of T10 on the OScope. I'm not sure where to look for audio signal prior to the AF gain pot.

73,

Doug - N9XTF

Doug,

Usual divide and conquer techniques apply. Since you've validated wiring at this point, check for correct voltages (all of them) coming off the new Sherwood PS board. Since you cannot see or detect audio on the high side of the AF control, that points to the new PS.

In addition to the scope check, you may also want to try tapping audio from the R-4C's AF control with a homebrew signal tracer. For quick checks, I often use an old RadioShack pocket amp with a 9V battery but almost any cheap amp can be made to work this way. My amp was designed with a 5K pot right at the input with no coupling, but I modified it with a 0.22 uF input coupling cap and a 100K series input resistor. Battery operation is nice since there's no opportunity for ground buzz/hum to seep in. Except in Hi-Z cases (e.g., right after a diode detector) this arrangement blocks all DC and doesn't load down the circuit as it's just bridging the source.

Paul,

The first thing I did was to verify the voltages. I have +12VDC +10VDC +150VDC and -70VDC at the power supply board. I also double checked that I had +10 VDC on the first wafer of the mode switch. I carefully labeled all wires as I pulled them off the old power supply board. I have checked and rechecked but my fear is that I am missing something simple.

I appears that the receiver is working as expected, IE I can tune to 40M with a short wire attached, tune through the band and watch the S meter deflect as normal receive operation. I just can’t find the darn audio.

I’ll do some more poking around, thanks for all the info!

Doug -

OK, that narrows it down pretty well. That is the OUTPUT of the detector section. The secondary of T10 is the INPUT of
the detector circuit.

There was a shielded wire coming from the front side of the first wafer of the MODE switch that 'used to' go to the TOP
of the AF GAIN pot. Is it still connected?? Then there should be a wire (shielded) from the CENTER terminal of the AF
GAIN pot to the INPUT terminal of the Audio Amplifier.

My next guess is that the TOP of the AF GAIN control is grounded. Either through a short in that shielded wire, or
perhaps connections reversed?? If you disconnect the wire from the CENTER terminal of the AF GAIN control to the input
of the AF Amplifier and touch this wire with your finger you should get a good hum or buzz.

Garey et. all,

I OWE EVERYONE ON THIS LIST A HUGE APOLOGY FOR TAKING UP IMPORTANT BANDWIDTH BECAUSE I AM SIMPLY A DERELECT!!!

I was reading your response while I was waiting to pick my son up from track practice. I went through your comments about 10 times and I mentally went through my wiring changes about 10 times. It occurred to me that the receiver looked like the AF gain pot had been replaced because the shielded cables going to the pot had been unbundled and were not tucked into wire loom like my other R-4C. So I rushed home and looked at the working R-4C that's turned upside down sitting next to the one that isn't working and realized that I had been chasing the wrong cable, the wiper and hot side cables were reversed from the previous golden screwdriver. I only removed the wiper connection and left the shield connected. This coupled with the picture I took verified this.

Now the stupid part is is that I set a "good" receiver next to the bad one so I could trace wires, check common voltages, signal inputs etc. I have no excuse for not comparing the AF gain pots, one is a blue and one is a red so its very obvious. If you had not said to check the pot for wrong wiring I would have taken it to Joe's house and he would have picked it up in two seconds and I would have totally wasted his time!

Again, I absolutely apologize to the list and open it up for useful traffic!

Maybe this is source of the culprit. In doing resistance chart checks on all the tubes after all the other testing and lifting of CR15 and so on before, i found that Pin 7 (input grid) of V10B (VOX Relay Control) is at 27 ohms instead of 500K. It's almost a dead short to ground. All the controls noted under the resistance chart were set properly.

That would explain why it keys but then drops out after a half second. That would also explain why the VOX CW delay control has little influence on the amount of delay. Also would explain why CW spot won't stay keyed. I use PTT on SSB and AM so never noticed whether it would drop out.

It doesn't explain why, in Tune, the signal is audible in a separate RX and can be peaked but there is no power output with any position on Gain except in the RX. But then transmit and full output shows on the W4 and receiver's S meter.

I can kinda see how an almost direct short to gnd in V10B could draw enough current to decrease voltage on V9. Kinda but not entirely satisfactory.

What do you think? I know I haven't found what makes the resistance at pin 7 of V10B so low.

Bob -

I can't see anything that could cause that other than a shorted C92 (unlikely), short between Pins 7 and 8 wiring, or a
shorted tube (most likely).

I can't follow it all the way yet, as I have to go out, but will look at it later if you don't find the problem first.!!

I gotta go, but if that resistance is really 27 ohms, V10B should be conducting and the relay pulled in all the time.

Yep, that did it! Voltages on V9 back up to 'normal' with V10 pulled.

I can see why V10 didn't conduct all the time. With no load or input, there was just enough residual or stray resistance to keep it 'open'. With it, the tube went to ground. Without it, the tube went back open.

I checked for shorts in the tube with my Sencore MU-150 tube tester. It didn't show any shorts but the tube tester isn't real world, of course, and not always truly indicative of a situation.

I don't have another 6EV7 but will order one just case. In one version of the manual---i don't know if earlier or later than the version on your CD---there was a suggestion to use a 6EQ7. The suggestion might have been in service bulletin or something. Any recommendations on that idea?

One of the fellows here on the list first suggested it might be a gassy 6EV7. Sounds pretty good now although I still need to check the components in the 6EV7 circuits as a possible cause.

Any thoughts? Bob

Doug -

Don't feel bad. This is how I find a lot of problems. Tube devices have lots of interconnecting wires going to small boards. Most of my training in electronics was with PCB's, though we used cables quite a bit, back in the day. A good technician remembers past failures and applies them to future problems.

Your odyssey helps the rest of us to avoid the same error. I used to read old tech logs back in the 1970s to gain insight as to most likely failure modes. This still works today.

73,

Steve Wedge, W1ES/4

Garey et. all,

I OWE EVERYONE ON THIS LIST A HUGE APOLOGY FOR TAKING UP IMPORTANT BANDWIDTH BECAUSE I AM SIMPLY A DERELECT!!!

I was reading your response while I was waiting to pick my son up from track practice. I went through your comments about 10 times and I mentally went through my wiring changes about 10 times. It occurred to me that the receiver looked like the AF gain pot had been replaced because the shielded cables going to the pot had been unbundled and were not tucked into wire loom like my other R-4C. So I rushed home and looked at the working R-4C that's turned upside down sitting next to the one that isn't working and realized that I had been chasing the wrong cable, the wiper and hot side cables were reversed from the previous golden screwdriver. I only removed the wiper connection and left the shield connected. This coupled with the picture I took verified this.

Now the stupid part is is that I set a "good" receiver next to the bad one so I could trace wires, check common voltages, signal inputs etc. I have no excuse for not comparing the AF gain pots, one is a blue and one is a red so its very obvious. If you had not said to check the pot for wrong wiring I would have taken it to Joe's house and he would have picked it up in two seconds and I would have totally wasted his time!

Again, I absolutely apologize to the list and open it up for useful traffic!

Doug - N9XTF

When I replaced my power supply board on my R4C, I had to replace my audio amp also using the Sherwood audio amp because the new power supply board from Sherwood is not compatible with the stock Drake audio amp. They both work great.

Cool! I don't see the path, but there is a lot of switching going on in there. What does Pin 7 show to ground with the
tube out??

6EV7 is pretty easy to find, and not expensive. The 6FQ7 however is an audio favorite and so considerably more
expensive. The FQ was only used because Drake couldn't get sufficient quantities of the EV for production. The EV was
originally used for TV Remote controls, the old 'clunk-clunk-clunk' type!! It wouldn't hurt to get an EV, having a
spare almost always obviates the need for one! :-)

18992. New Drake TR-4CW-RIT Owner

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-27 02:51:01 UTC
From: Whitebear1122
Topic: 18933 Message: 18992

Well after some 43 years I finally own a 4C station. I just bought a gorgeous TR-4CW-RIT and AC-4 power supply. It arrived today and I had the thrill of pulling this beauty out of the box and being blown away by the great condition. It hasn't been often that I've been wow'd by the condition of a radio. I'm listening to 20 meter cw and ssb right now on it. I need to print out the manual to read up on how to tune it so I'll try it out tomorrow night on 20m. I might look for an original TR-4CW-RIT manual as I've always enjoyed having an original manual with a radio. I store the manuals underneath the radios for quick access.

I heard there is a Saturday Drake net on 40m. I'll have to look into that!

I've been curious about the 500 Hz filter and RIT. Looks like the TR-4 will be nice to operate on CW. I could easily zero beat the other station, then use the RIT to slip up the band a bit to put the signal smack dab in the 500 Hz passband. Sweet!

A long time ago, some 43 years ago, I was in the Navy overseas and would look read QST from cover to cover, and I would spent a lot of time dwelling on the Amateur Electronic Supply advertisements showing Ray Grenier sitting at the helm of a fabulous Drake station. I sure dreamed about that station but I wasn't in the right place or right time. Guess 43 years later is the right time and right place :)

Did Drake ever have Drake QSL cards? I remember WRL did, Hammarlund did. Wonder if Drake ever did.

Finally Drake,
73, Scott WA9WFA

Scott,
It's about time!!!! Now you'll learn what a lot of us already knew, it's all good in one way or another, and Drake has it's good points too?? Glad to see you on the group, there's a lot of collective knowledge of the old Drakes on here, and it's freely shared as on many of the old radio lists.

Welcome to DrakeRadio!! You will fit right in.
73,
Don, WB5HAK

Scott:

Another grey box Cedar Rapids convert! Welcome aboard!

Some years ago Ray sent me a copy of the original ad pic at the helm of that Drake station on the Design Industries desk. As a VHF DX'er I drooled over the TC-2/TC-6 combo on the shelves above the B-line those many years ago. Talking with Ray on 2m one night some 30 years later during some enhanced tropo over the Great Lakes, the talk quickly turned to Drake and his famous ad. His pic turned up in the mail a week later!

I'll do what I can to get it scanned and posted to this group. It's what drove me back into Drake. Just beware – Miamisburg black boxes are contagious!

By the way, our gracious host here eagerly participates on threads that deviate from "strictly Drake" and you'll get used to the friendly banter you do not see elsewhere.

Subject: [DrakeRadio] New Drake TR-4CW-RIT Owner

Well after some 43 years I finally own a 4C station. I just bought a gorgeous TR-4CW-RIT and AC-4 power supply. It arrived today and I had the thrill of pulling this beauty out of the box and being blown away by the great condition. It hasn't been often that I've been wow'd by the condition of a radio. I'm listening to 20 meter cw and ssb right now on it. I need to print out the manual to read up on how to tune it so I'll try it out tomorrow night on 20m. I might look for an original TR-4CW-RIT manual as I've always enjoyed having an original manual with a radio. I store the manuals underneath the radios for quick access.

I heard there is a Saturday Drake net on 40m. I'll have to look into that!

I've been curious about the 500 Hz filter and RIT. Looks like the TR-4 will be nice to operate on CW. I could easily zero beat the other station, then use the RIT to slip up the band a bit to put the signal smack dab in the 500 Hz passband. Sweet!

A long time ago, some 43 years ago, I was in the Navy overseas and would look read QST from cover to cover, and I would spent a lot of time dwelling on the Amateur Electronic Supply advertisements showing Ray Grenier sitting at the helm of a fabulous Drake station. I sure dreamed about that station but I wasn't in the right place or right time. Guess 43 years later is the right time and right place :)

Did Drake ever have Drake QSL cards? I remember WRL did, Hammarlund did. Wonder if Drake ever did.

Finally Drake,

Hi Gary (and everyone else!)

Wow what a great (active!) group and what a fast response to my question :)

Thanks Gary - all received - what a star :) - really appreciate it !

I guess I should have mentioned that the reason for the post title was that the radio is 'for repair' unit hence the title restoration :)

From the circuit and others postings it looks pretty reliable and the technology is pretty straightforward so hopefully not too many issues to resolve as long as its complete and nobody else has 'tried' to fix it. I specialise in repairing / resolving issues where other tech's (good and bad) have tried and failed :) . I pick the TR-5/PS-75 unit(s) up tomorrow, once I've cleared my bench of an FT-1000D with a particularly tricky ALC problem (not the usual swr/lpf/tuner unit diode problem) I will dive into the TR-5. I will post some initial findings and perhaps some photo's (can I do that?).

I think I might have the Drake bug now alongside the Hethkit/Ten Tec /Swan one, which might be problem - I've got my eye on (this time working) TR-7 with power supply, so lets see how that goes!!

Thanks again,
Chris

Yes, a rare bird! I have sent a schematic under separate cover, which is apparently even 'rarer' in the wild! :-) It
was large format, so was easily separated from other docs.

I've not operated a TR4Cw/RIT before, but if you do what I think you're saying you'll do, won't that put your signal off the other station's frequency?

If the TR4Cw/RIT is like every other transceiver I know about, you need to tune the other station to a pitch that matches the offset...and I think, but am not sure, that the Drakes use 1 kHz. You could then use the RIT to change the pitch slightly or chase the other guy if he's drifting, etc.

If you tune so the other guy's tone disappears - is 0 Hz - then you'll be off his frequency by the amount of the offset.

I think of "zero-beating" as tuning two signals so that the beat note between them disappears - say using Spot to tune a separate transmitter to a received signal. Tune for minimum "wawawaawaaawaaaa" between the two signals and that is zero beat.

Or am I off-base here?

Morning all;

I am guessing a lot of us here were inspired (or at least envied) that old QST/AES ad with Ray sitting in front of his Drake line.

A Google search reveals Ray just retired within the last few weeks from AES after more than 50 years with them. He's already working again....with West Mountain Radio.

Here's the link;
http://fdlhams.org/assets/2014-feb_news.pdf

They goofed up his call on the right hand side of the page but got it right in the President's comments on the left.

Funny – I didn't remember his hair being white.....then I looked in a mirror.....right!

Pin 7 of the 6EV7 without the tube itself shows -4.2 Volts.

Switch paths are nearly a complete mystery to me. My only guidance is a meter and sometimes s scope. But I don't know looking at a schematic whether you're looking at the front or back of a switch wafer. It's especially evident on radios from the 20s - 40s, assuming you can find a schematic at all. Symbology of components changed through the years, and some manufacturers didn't want others to copy their designs.

What does the voltage on Pin 7 tell you?

tube out??

6EV7 is pretty easy to find, and not expensive. The 6FQ7 however is an audio favorite and so considerably more
expensive. The FQ was only used because Drake couldn't get sufficient quantities of the EV for production. The EV was
originally used for TV Remote controls, the old 'clunk-clunk-clunk' type!! It wouldn't hurt to get an EV, having a
spare almost always obviates the need for one! :-)

Bob -

Tells me you have a bad tube..... I thought your first post said you had swapped the tube. That negative voltage is
plenty to cut off V10b, de-energizing the relay. Rectified sidetone from V10a is plenty to overcome that bias and cause
the tube to conduct, pulling in the relay. UNLESS the plate voltage is too low on V9!! :-)

Certainly an odd set of symptoms. By dragging down the Plate voltage for V9 it led me down a garden path! :-)
Interesting, because loss of the signals generated by V9a, with the other symptoms sure suggested loss of that tone.
Once again, the horses beat the zebras! :-) I still don't see how that occurs, it'll take some research.

The switches on Drake schematics show the wafers seen from the front, and in the full CCW position. Even the rear side
of wafers are shown as viewed from the front, a sort of 'x-ray' view. The biggest problem in tracing through them is
figuring which fixed contacts are 'long' and so reach the 'lower' part of the wiper. I made up some small, transparent
overlays with lines on 30 degree intervals so I can see what happens when the switch is rotated. Another thing that
helps is a photocopy of the schematic that you can highlight with various colors to show connections made in each position.

Good ideas on following the switches, Gary.

I subbed V9 originally, not the 6EV7. I don't have another 6EV7 to sub.

The measurement I just sent was of Pin 7 on the empty 6EV7 socket. Should I have measured Pin 7 of V9 instead? Been checking so much so fast maybe (probably) I got mixed up. Bob

Tells me you have a bad tube..... I thought your first post said you had swapped the tube. That negative voltage is
plenty to cut off V10b, de-energizing the relay. Rectified sidetone from V10a is plenty to overcome that bias and cause
the tube to conduct, pulling in the relay. UNLESS the plate voltage is too low on V9!! :-)

Certainly an odd set of symptoms. By dragging down the Plate voltage for V9 it led me down a garden path! :-)
Interesting, because loss of the signals generated by V9a, with the other symptoms sure suggested loss of that tone.
Once again, the horses beat the zebras! :-) I still don't see how that occurs, it'll take some research.

The switches on Drake schematics show the wafers seen from the front, and in the full CCW position. Even the rear side
of wafers are shown as viewed from the front, a sort of 'x-ray' view. The biggest problem in tracing through them is
figuring which fixed contacts are 'long' and so reach the 'lower' part of the wiper. I made up some small, transparent
overlays with lines on 30 degree intervals so I can see what happens when the switch is rotated. Another thing that
helps is a photocopy of the schematic that you can highlight with various colors to show connections made in each position.

Yeah I still don't quite understand loss of tone unless, with the 6EV7 going dead and the 12AX7 having low plate voltage, it either was not generated or, if it did, never made it to or back back from the receiver.

What is evident is that when I pulled the 6EV7, the plate voltages on the 12AX7 went back up to normal. I theorized on why I thought it did but I could be off base too. But clearly that was the physical (electrical) result of pulling the tube. It or something in its circuit affected V9. Bob

Ok Gary I just went back and measured the voltage on Pin 7 of V9. I think that's what you meant me to do in the first place.

That voltage is -.01. That won 't do much of anything to anything. Does that make sense?

Sorry for the confusion. Bob

19006. RE: TR-7 S-Meter readings with narrow SSB filter

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-28 02:03:02 UTC
From: <w9dz@...>
Topic: 18936 Message: 19006

Calibrator signal is essentially the same through all the filters (6.0, 1.8 and 300Hz) with the exception of the standard SSB filter.
After transmitting for a bit yesterday I thought the problem had corrected itself but it's back this evening.
The reason I asked about testing the PIN diodes was prompted by some Google searches and remarks from folks who said it required passing RF through the diode and application of DC bias. I'll take a look with my DVM and see what it shows. No, I don't have extender boards. I do have the service manual so I shouldn't have a problem locating the correct diodes.
Thanks.

Put V10 back in and measure the voltage at Pin 6 and 7. I assume you are in SSB MODE when you're making these
measurements, GAIN at minimum. Measure in TUNE and again in SSB. Check the Pin 1 and Pin 6 of V9 in both positions.
Also measure C107 + terminal in each of these positions.

Recheck Pin 7 of V10 resistance to ground, and again with meter leads reversed.

True, but at this point were looking for an open or shorted PIN diode. Easy to check with a DMM, especially if it has a
diode test range. (Diode symbol on range switch.) Also be sure and check the -5 VDC supply. (Typically -3.5 VDC)

19009. T-4X "Asheville" Radio

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-28 02:57:51 UTC
From: Steve Wedge
Topic: 19009 Message: 19009

This is the one that I've been working on.

Obviously, there's a bad connection in there somewhere - had it upside-down and it wouldn't put any RF out. Jiggled the carrier balance again and not much. Jiggled V8 and got power again. I've already lightly Cramolined the tube pins after running them all through the straighteners. Might be time for the old loosen/tighten screws routine.

Seemed to have low power out in TUNE. Cranked all the way, I can get about 30W. May try looking at the audio oscillator tomorrow or this weekend.

All power out seemed low. Put in a NOS 12BY7 and have more power. Now seeing the meter peg to get over 100W. Will have to check the meter resistors, as I think they're off. Evidence of tomfoolery on the metering board.

I can get about 90W out on 28.8 MHz. Good enough. Those finals were sold to me as pigs in a poke, so I'm not surprised. Still enough.

No output at all on 40 now and there was before the Big Splash. Will have to check the caps in the bandswitch. Another 18.1 crystal didn't make it louder.

Oh - the name. I won this one in an eBay auction and somehow, PayPal told the seller to ship to my son in Asheville. To his old apartment. After it made the circuit around Asheville, looking for Dan, it was returned to the seller, who then reshipped it to me. Good thing it's in nice cosmetic shape.

More, as it develops. I was going to do the other T-4X after this one, but I think I'm going to work on receivers for a while and crank them out. Have two R-4's and two R-4A's to get through.

Put V10 back in and measure the voltage at Pin 6 and 7. I assume you are in SSB MODE when you're making these
measurements, GAIN at minimum. Measure in TUNE and again in SSB. Check the Pin 1 and Pin 6 of V9 in both positions.
Also measure C107 + terminal in each of these positions.

Recheck Pin 7 of V10 resistance to ground, and again with meter leads reversed.

Bob -

Not a problem, this is what we're here for. Hopefully others are learning what NOT to do from our (my) dithering! :-)

I do NOT see any way that anything to do with V10 can affect the plate voltage on V9a and V9b. All three pins of V10b
could be tied together and grounded, and the only thing that would happen would be that the relay is pulled in. There
is no connection that I can see, even assuming a failed component, that V10 can affect the plate voltage on V9.

All your early symptoms can be explained by a loss of sidetone signal from V9a. The cause of this loss is the starving
of V9 by reduced plate voltage. The voltage stays solid on C107, which is the common plate supply point for V9a and V9b
-ONLY-. Each plate of V10 has it's own plate resistor directly to the +250 VDC bus.

What happens to the voltage on C107 when V10 is plugged in? If it stays steady, then monitor the voltage on Pin 6 of V9
with V10 OUT of the socket. Should be 140 VDC or so. Then plug in V10. Does the voltage drop immediately, or does it
take 10 seconds or so as V10 warms up???

Anybody paying attention out there????????? Any ideas??????

19012. Re: R4C Filter Mods

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-28 11:35:41 UTC
From: Chris Pickett
Topic: 19012 Message: 19012

Hi Guys,

I have a R4C and have some new filters for adding to the Rxr which I am sure will improve this already fine RX.

I have the INRAD GUF-1 and also two Sherwood Filters one for LSB and one for USB, I am fairly sure these replace the existing sideband filters already installed in the RX.

I wonder if anyone in the group has a set of installation instructions that they could scan and forward to me or indeed point me in the right direction please,

Kind regards 73

Make sure the Sherwood filters aren't for a TR-4. The filters in the R-4C are not marked lower or upper because the receiver only uses one filter at each position, such that you have one and only one 2.4 (or is it 2.8?) SSB filter from the factory.

Subject: [DrakeRadio] Re: R4C Filter Mods

Hi Guys,

I have a R4C and have some new filters for adding to the Rxr which I am sure will improve this already fine RX.

I have the INRAD GUF-1 and also two Sherwood Filters one for LSB and one for USB, I am fairly sure these replace the existing sideband filters already installed in the RX.

I wonder if anyone in the group has a set of installation instructions that they could scan and forward to me or indeed point me in the right direction please,

Kind regards 73

Chris

Installing the GUF-1 filter is quite simple actually. The INRAD GUF-1 filter package contained instructions and a drilling template. If you do not have the installation instructions and drilling template, write INRAD and ask them if they would send you the instructions via e-mail.

The new INRAD GUF-1 filter installs in the same place as the original 8Khz BW First IF Xtal Filter. With the top cover removed, the receiver upright and the front panel facing you, the original 8Mhz BW first IF xtal filter is located to the right of T3 and T4. It is shown in the R4C manual, Figure 5-1, as the "8Khz BW First IF Xtal Filter". As stated above, the original 8Khz BW First IF Xtal Filter is removed and the new INRAD GUF-1 filter is installed in it's place. Installing the INRAD GUF-1 filter should take about 30 to 45 minutes time.

The factory sideband filter is located below the chassis towards the rear. Depending on the number of filter select positions on the front panel MODE switch determine where the "AM" filter is installed. The lowerr serial number R4Cs, with only 4 filter select position, the AM filter is installed along with additional CW filters, on the rear panel. The higher serial number R4Cs, MODE switch has 5 filter select positions, additional sideband and CW filters are installed on the rear panel and the AM filter is installed inside and directly above "V3".

Steve is correct, the R4C has only one filter for both USB and LSB. Sideband selection is accomplished using the BANDPASS TUNING control on the R4C's front panel. If you have 2 filters, one marked LSB and the other marked USB and you have a T4XB or T4XC, save them as spares or just sell them on eBay, they will be of no use to the R4C receiver.

Ok will do the test from last night's email and this one today. I'll call them Tests 9 and 10! Ha.

Won't make any definite conclusions until then. I see all the things you're saying, both in my mind and on the schematic. I do know I have no side tone and VOX drops out quickly. Whether the two are related or not, I don't know. I do know voltage rises on V9 when V10 is pulled and it should have no effect. I do know the one resistance at V10 Pin 7 is low and there are only 4 components associated with it.

Having said that, I will do these 2 other tests and see if the results replicate themselves. Maybe I had bad eyes at the time.

BTW, I put a fresh battery in the DMM last night even tho it probably didn't need it. I was recording Comet SL-9 back in 1994 with a strip chart recorder and a battery powered home brewed integrator back and then just as Fragment S1 or S2 hit Jupiter, the battery began to die and the recording became a straight downward line and i lost about 2 minutes of 'signal'. I learned my lesson about 9V batteries then. Bob

Bob -

Not a problem, this is what we're here for. Hopefully others are learning what NOT to do from our (my) dithering! :-)

I do NOT see any way that anything to do with V10 can affect the plate voltage on V9a and V9b. All three pins of V10b
could be tied together and grounded, and the only thing that would happen would be that the relay is pulled in. There
is no connection that I can see, even assuming a failed component, that V10 can affect the plate voltage on V9.

All your early symptoms can be explained by a loss of sidetone signal from V9a. The cause of this loss is the starving
of V9 by reduced plate voltage. The voltage stays solid on C107, which is the common plate supply point for V9a and V9b
-ONLY-. Each plate of V10 has it's own plate resistor directly to the +250 VDC bus.

What happens to the voltage on C107 when V10 is plugged in? If it stays steady, then monitor the voltage on Pin 6 of V9
with V10 OUT of the socket. Should be 140 VDC or so. Then plug in V10. Does the voltage drop immediately, or does it
take 10 seconds or so as V10 warms up???

Anybody paying attention out there????????? Any ideas??????

Date: 2014-02-28 15:17:33 UTC
From: whitebear1122@...
Topic: 606 Message: 19019

Last night I fired up the TR-4CW-RIT for the first time and had a nice hour long QSO on 20m SSB with a fellow up the New England way. The TR-4CW-RIT worked great, was stable, and I didn't have to touch the dial at all during the entire QSO. I don't think he was as impressed with my running Drake equipment as I was . hi hi

I did notice the radio gets very hot, rear left, over the sweep tubes. Radio came with an externally mounted fan on the rear using tie wraps, and externally powered. For the time being I set a muffin fan w/ rubber feet on the cabinet and it quickly cooled it down.

Are you TR-4 and T-4X guys powering fans off of filament voltages or externally.
Just wondering if there is enough headroom on filament current to power a small fan. I am familar with rectifiers and doublers so I can get the fan powered with the right voltages as long as I have adequate source current.

I would also like to buy a TR-4CW-RIT manual if anyone has one available.

73, Scott WA9WFA

Hi Scott,

Yes, by all means, cool those rascals down...!

An exhaust fan---i.e. one that draws air UP from the final amp cage---seems to work best. I use a small computer fan here, with its own wall wart plug-in supply.

Some years ago I made actual side-by-side tests of PTO drift in my T-4X with, and without, the cooling fan: the results were actually easily measurable, & the incorporation of any fan is certainly worth the little effort it might take to install---not only for the longevity of those sweep tubes, but the entire rig itself!

19022. R4A Preselector coils

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-28 15:17:12 UTC
From: <rochep@...>
Topic: 19022 Message: 19022

I am in cleaning up a "new" R4A and I have a question about the preselector coils. I don't know how much UP and DOWN play there should be for the "iron" cores that go into coils. What does "all the way down" or "all the way up" look like? I can gently pull them "up" or "down" a bit while turning the knob, but this is obviously not a good strategy. If the cores ever "stick" in the coil, is there lubricant that people use? I am new to this, this is my first Drake, it seems to work OK but I could not resist tearing it apart cleaning, studying it, etc…

Ok Gary, here are the measurements for the two emails.

Test 9. V10 in, SSB and TUNE modes, GAIN minimum, VOX off, Dummy load.

SSB mode: V9, Pin 1 33.1 V, Pin 6 75.6 V, C107 210.5 V
TUNE: V9, Pin 1 32.2 V, Pin 6 71V, C107 197.8 V
Resistance: V10 Pin 7 - 9.9M, reversed leads 5.3M

Test 10. C107 w/ V10 in - 215.7 V
V9 Pin 6 w/o V10 - 250.6 V
V9 Pin 6 w/ V10 in - 75.4, immediate drop in V
That's the latest. Bob

From: Steve Wedge
Topic: 19022 Message: 19025

Paul, the problem is most likely due to slippage of the Jackson Drive, right behind the PRESELECTOR control. Sometimes, people re-lube them without knowing that the drive needs a certain amount of friction from the grease in order to operate properly. There are also times when a groove has been worn in the shaft from years of the ball bearings riding on the same spot. I do believe WB4HFN's website has one possible fix for that problem.

If you do take it apart and clean it, use something similar to wheel bearing grease (I.e., really thick and viscous) when putting it back together. The whole assembly is held in place by pressure from the slug rack. It can be finicky but once you get it set up, that should be the end of it.

I just got an R-4A in that's sticking toward the lower end, so I'll be doing the same thing shortly...

Paul -

Welcome to the fold.... First question is: Is this an 'early' or 'late' R-4A?? There ARE significant differences. s/n?

Do you have a manual?? Can't tell the players without a scorecard!

When the PreSelector is turned fully clockwise, the top edge of the slugs should extend 9/16" above the top of the fiber
tubes. They should all be the same. Turned fully counter-clockwise, the top edge of the slugs should be just below the
top of the tube.

I've never seen a need to lubricate them. The drive mechanism for the 'rack' has some play in it, but is of no
consequence. Answer, "Don't pull up or down on the rack. Use the knob!'

I use a separately powered exhaust fan that sits on top of the cabinet to draw the heat off the PA tubes. However you set it up, use the fan to pull the air off, not blow on the tubes.

Subject: [DrakeRadio] First TR-4 SSB QSO

Last night I fired up the TR-4CW-RIT for the first time and had a nice hour long QSO on 20m SSB with a fellow up the New England way. The TR-4CW-RIT worked great, was stable, and I didn't have to touch the dial at all during the entire QSO. I don't think he was as impressed with my running Drake equipment as I was . hi hi

I did notice the radio gets very hot, rear left, over the sweep tubes. Radio came with an externally mounted fan on the rear using tie wraps, and externally powered. For the time being I set a muffin fan w/rubber feet on the cabinet and it quickly cooled it down.

Are you TR-4 and T-4X guys powering fans off of filament voltages or externally. Just wondering if there is enough headroom on filament current to power a small fan. I am familar with rectifiers and doublers so I can get the fan powered with the right voltages as long as I have adequate source current.

I would also like to buy a TR-4CW-RIT manual if anyone has one available.

Bob -

OK. That's better, I was really concerned about that 27 ohm reading at Pin 7 of V10!

By the way, 'No sidetone' and 'VOX drops out quickly' are both definitely related to V9a and each other. The SIDETONE
is what 'holds' the VOX in for the CW MODE. In SSB, the voice modulation is rectified and integrated to 'hold' the VOX
in. The R107, C115, CR17 network is what 'pops' the VOX on for the first half-second.

The resistances in just about all the points shown in the chart are affected by the 'polarity' and 'magnitude' of the
ohmmeter voltage. There are almost always multiple paths, some including semiconductors. So aside from polarity
differences, good DMMs use a low enough voltage on the ohmmeter ranges that semiconductors are NOT turned on, reducing
the effect on readings.

Ah, strip chart recorders... The techs used to have contests to see how far they could shoot paper out of the launch
recorders!. :-)

Bob -

OK, I think we're getting close..... (Again!) :-)

Check the voltage on both ends of R90, with and without V10 in the socket.

Thanks guys,

It is S/N 5028, so a late model R4A with 11 tubes. Yes, I have a manual. The distances you mention seem about right, so I am probably good. I am loathe to fix something that ain't broken. This baby looks GREAT, but I did not operate it long enough to know it PLAYS great. I was sort of scared having it run very long with the original electrolytics in there. I used to be in the school of replace electrolytics even before you plug it in, but from what I read many Drake users simply keep the original electrolytic can going until something tells them to replace. Would that same advice be for the 3 other electrolytics in there?

NO, I would replace the electrolytics if it were mine and I planned to use it. Ask one of our list members now looking for a replacement power transformer for his. They are MUCH more expensive than electrolytics, IF you can find one. Just my .02 worth, worth about what you paid for the advice though.

I have a T4XB and TR-4, I use fans on both. My fans are AC operated rated at 220 volts but run on 120. They move plenty of air to keep the transmitters cool but make no noise. When I got them I got protective grills for both. I mount them using foam weather stipping from the hardware store. I ran a strip around the periphery of each fan. This gives a little vibration isolation and seals the bottom of the fan to the top of the chassis cover. The fans are not fastened to the cover but there is enough friction from the stipping to prevent them from moving around. I have a cord switch on each fan with the switch pulled around under the unit. BTW, the same fans work fine on the R4B sitting over the power transformer. Without the fan the transformer gets too hot to touch, with the fan it stays cool. All fans blow OUT.

No, I don't trust old electrolytic caps at all
especially if the radio has been out of service for a while.
New ones are available and not expensive. If no one has
suggested it yet try Hayseed Hamfest for can electrolytics,
Tom makes brand new ones (not re-stuffed old cans) and is
reasonably priced. I've used a number of his caps and have
been very satisfied.

Paul -

I would never tell anyone to NOT replace electrolytics in old gear. Even Drake....

However, (there's always a 'however',) I have had/used literally hundreds of pieces of Drake gear over the last 50+
years, and I just had my first electrolytic capacitor failure last year. The hum increased slightly, and then a little
more. Sure enough, the ESR of the second stage B+ filter had gone to about 300 ohms, resulting in considerable hum. A
new Hayseed cap and all was well again.

That said, I have NEVER seen a power transformer failure in either receiver or transmitter, EXCEPT where the 750 mA AC
fuse had been replaced with a 10A fuse, a piece of #00 solid copper wire, or simply wired across the fuseholder. The
caps Drake used are very well behaved, and just dry out with age. 'When' seems to be affected primarily by temperature
and perhaps humidity. I have repaired radios, with blown fuses, and a shorted electrolytic, usually the first stage of
the HV supply. These from users who were smart enough to seek help when the fuse blew, instead of just putting in a
bigger one!! :-)

High ESR in the BIAS supply cap can present as some weird behavior, as can the one on the Calibrator board in the B
Series. I think everyone knows about the high 'backwave' on the sidetone caused by the can cap in the T-4X(any). The
AC-4 supply is also relatively free from capacitor failure. Again, the only transformer failure I have seen was caused
by fuse 'substitution'.

So aside from the 'inconvenience' factor, almost assured by Murphy to be significant, I see no need to 'shotgun' replace
electrolytics in Drake gear. But again, no harm will come from replacing them, as long as you (or someone else) does
the job correctly!

19038. TR-5 Restoration

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-02-28 19:30:15 UTC
From: <chrismortlock1@...>
Topic: 18930 Message: 19038

Hi, So it starts :)
I've picked it and the PS75 power supply up (will post pictures as soon as I can get some decent ones taken). Some really interesting documentation, firstly (although not stated in the advert) its got a full original manual together with a circuit diagram as well !!!! (but thanks anyway Gary much appreciated!), it also has an original print advert, a lot of handwritten notes as well. Its serial number is 1099 - no idea where that places it in age terms, also has documentation for a Noise Blanker which looks like its been installed.It also has something I've never seen before an interim manual. This is type written with photo's etc. but is stapled together as obviously is prior to the 'proper' manual as it says "The final version of the manual for the TR-5 is still in process. You will receive a copy when it is printed provided you return the enclosed warranty card. Complete service information will be included in the final manual'. The original owner (I'm the third apparently!) obviously did as I have both :)

Also and more interestingly a letter written to Drake (Mr William A Frost, service manager) in 1995 detailing the fault, together with their reply back on the 19th July 1995. I haven't turned it on yet to establish if this is the fault but the letter to drake talks about "essentially there is no usb or lsb reception or transmission and no audio output" - then talks about a failure on usb closely followed by lsb failing.

The response from Drake suggest checking cables, especially the coax cbale around the BFO board, then U-801 MC1496 on the tx/rx mixer board, then q-806 (2N4427) and 2N5109 (Q-802).

So we shall see what happens when I start to fault find in the next day or two if this fault still exists or another...

Condition wise its looks good but very dusty (for very read filthy), all looks original, and everything seems to move well. It was being sold by a radio club after clearing out (Sadly) from a silent key, and they believed it was simply put away in his shack and sadly never used again.

I also picked up an HW-7 (more of that later) and a wonderful (non DRAKE) high power ATU (CAPCO 3000), again in a very dirty but original condition, both stated as working but we shall see, and a DAIWA 30A power supply - you can never have enough power supplies can you :)

Will update when I get started - excited - having to stop myself diving straight in :)

73's
Chris.

You will like that schematic in that you can blow it up and read the stuff.

Its serial number is 1099 - no idea where that places it in age also has
documentation for a Noise Blanker which looks like its been installed
In both cases go to _www.wb4hfn_ (http://www.wb4hfn) and the Drake stuff.
On the left is serial number data base, if you still have the small tear
off cardboard "tag" that gives the serial number and check out date yours
could be in that base. Just email wb4hfn@...

The second thing ...you say it looks like NB has been installed. Pictures
under TR5 NB manual on WB4HFN.

Thanks to all that answered.

I have dug out the filters and mailed Rob Sherwood for some assistance on those.

Inrad GUF-1 filter instructions have been forthcoming from another source and looks to be an easy change out.

Next time I have some time I will get it done and let you know how I get on and if it makes much of a difference.

Subject: [DrakeRadio] First TR-4 SSB QSO

Last night I fired up the TR-4CW-RIT for the first time and had a nice hour long QSO on 20m SSB with a fellow up the New England way. The TR-4CW-RIT worked great, was stable, and I didn't have to touch the dial at all during the entire QSO. I don't think he was as impressed with my running Drake equipment as I was . hi hi

I did notice the radio gets very hot, rear left, over the sweep tubes. Radio came with an externally mounted fan on the rear using tie wraps, and externally powered. For the time being I set a muffin fan w/rubber feet on the cabinet and it quickly cooled it down.

Are you TR-4 and T-4X guys powering fans off of filament voltages or externally.
Just wondering if there is enough headroom on filament current to power a small fan. I am familar with rectifiers and doublers so I can get the fan powered with the right voltages as long as I have adequate source current.

I would also like to buy a TR-4CW-RIT manual if anyone has one available.

73, Scott WA9WFA

> Well after some 43 years I finally own a 4C station. I just bought a gorgeous TR-4CW-RIT and AC-4 power supply. It arrived today and I had the thrill of pulling this beauty out of the box and being blown away by the great condition. It hasn't been often that I've been wow'd by the condition of a radio. I'm listening to 20 meter cw and ssb right now on it. I need to print out the manual to read up on how to tune it so I'll try it out tomorrow night on 20m. I might look for an original TR-4CW-RIT manual as I've always enjoyed having an original manual with a radio. I store the manuals underneath the radios for quick access.
>
> I heard there is a Saturday Drake net on 40m. I'll have to look into that!
>
> I've been curious about the 500 Hz filter and RIT. Looks like the TR-4 will be nice to operate on CW. I could easily zero beat the other station, then use the RIT to slip up the band a bit to put the signal smack dab in the 500 Hz passband. Sweet!
>
> A long time ago, some 43 years ago, I was in the Navy overseas and would look read QST from cover to cover, and I would spent a lot of time dwelling on the Amateur Electronic Supply advertisements showing Ray Grenier sitting at the helm of a fabulous Drake station. I sure dreamed about that station but I wasn't in the right place or right time. Guess 43 years later is the right time and right place :)

Got a "new" to me 11-tube R-4A in the mail today. Got it cheap off eBay. Yes, you CAN get stuff off eBay for cheap. You must be patient.

The seller said it didn't work. Well, of course, it didn't! The 12AX7 was missing, as was the MUTE shorting plug!

Been listening to 40 SSB, contest, and it's holding its own. Oh, yeah: it came with 10 crystals on the back, and only 2 of them were for Chicken Band.

SCORE!

Ok Gary, still sitting at my test bench and just put down my DMM leads.

With V10 in, voltages at each end of R90 are 280 and 224.

With V10 out, voltages are 281 and 264, or, 40 v less at one end.

Hey Garey and all, On your advice I turned out the lights. You're right, the TR-4 is a pretty radio in the dark with the blue dial and meters and red indicators. I have to say one of the most amazing radio sights I've experienced is when I fired up my Johnson Viking Valiant with the 866 mercury vapor rectifiers. Wow what a sight when I keyed up and those 866's glowed bright blue like some nuclear reactor hi hi

Tnx for the manual information . Lucky for me the seller included his K4OAH service cd otherwise I'd be buying one from you. I printed out part of the manual this evening to learn how to safely tune up the radio. BTW, there is a big ARRL DX contest going on and I used the new Drake TR-4 to work Hawaii, Spain, and all over South American on 20 meter SSB tonight.

19051. TR-4C keeps going to TX

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-03-01 06:09:50 UTC
From: Steve VK2SJA
Topic: 18933 Message: 19051

Hello All,

Here is where I start crying HELP!

Quick back story:- eBay TR-4C "...worked last time I used it. RX was working. Didn't test TX". The usual story. Came without PSU. Sourced AC3 and immediately went to install ES4AC-3 PSU upgrade kit. During installation of PSU upgrade kit found that my AC3 only had a 110VAC transformer (only one primary winding).

Tried to test TR-4C in what I thought was RX mode. With upgraded PSU running from 240 to 110 step-down transformer. No attempt was going to be made to TX as step-down transformer would not be able to supply required TX current. No attempt was made to adjust BIAS.

Result. No audio at all. Fiddled around with controls not really knowing what I was doing (Yes, I do have a manual, and Yes, I did read it prior). Still no audio. After a couple minutes with power applied the fuse 2.5A in the step-down transformer blew. There was a "burst" of RX audio. Not sure if it was before or *after* the fuse blew. Discovered to my horror that the PA cage was very warm to touch. Concluded the radio had gone into TX.

Radio was then given the "Works Clean" (Steve style :-). Yes I now know that many frown upon this practice. Hayseed electrolytic capacitor kit fitted. Lot's of other cosmetic stuff. Complete clean and re-build of PTO. Radio now looks like brand new. Tightened all under chassis screws holding tag-strips and PCB's

Second AC3 sourced. This time transformer has both primary windings. Modify AC3 for 240VAC and install ES4AC-3. Found transformer sounded like it was going into saturation at anything much over 220VAC (250VAC 50hz at wall outlet). Modified PSU with step-down auto-transformer so that supplied mains is 221VAC and also threw in a soft-start module.

Checked R42, 43, 44 - 68ohm resistors. Found all mine were at about 75ohms. Replaced them.

(Sorry this is so long).

Today was the big day. Smoke test Number-II ! Same story (grin). Well almost.

Power radio on. Mode=SSB, TX-Gain at Min. Plate & Load both Min. Nothing for about ten seconds. Then S-Meter starts to move fairly quickly towards FSD. RX audio static heard for a few seconds at this point. The relay then "clicks", audio cuts out, and I assume that I am in TX mode. I turn power off at this point.

I have measured my PSU voltages at the feed-through's under chassis. All my voltages are low because of dropping the mains supply to 221VAC. Here are my voltages under RX load:-

+650Vdc => +632Vdc
+250Vdc => +225Vdc
BIAS => -70.6 to -34Vdc (currently set -70.6)
Heater => 11.25Vac

Are my voltages causing this problem? Any advice *very* gratefully received.

73 Steve
VK2SJA

No audio.

Richard:
Garey said put a VOM in line and change calibration resistor to match VOM reading. The meter is not linear so you have to pick a spot you want to be most accurate. My neighbor just did it and set it to be accurate at maximum grid or plate current. However, Garey suggests you set the accuracy at the required bias setting for the finals as this csetting is important to be accurate.

Topic: 19022 Message: 19055

Was listening with the radio last night after cleaning up, she sounds NICE. I think I have an alignment or other issue with the passband controls; on 4.8 kc and 2.4 kc CW signal is nice and strong, when I switch over to 1.2 kc it almost disappears, much much weaker, and 0.4 kc is even weaker. I am not worried, might be an alignment issue. The fuse in the radio is a 4 amp, THAT'S gotta go! Also PTO dial is OFF; when I slide the little red bar all the way to the left, it is STILL not on "0" when it should be. Might be a set-screw somewhere.

That passband control is wierd, all just adds "whooshiness" to my signal. But I do not have all the alignment tools needs (no decent signal generator, just an old Eico 324 and I have been told that is a horrible one).

The filter itself might have an issue.

When I bought my TR7 it had an intermittent 2.3 kHz filter. It was a strange effect of sometimes being deaf but not too severe.
I opened the filter, resoldered all joints and it has been fine all the time now.

Just one test you could do. With the handle of a screwdriver gently knock on the filter and see what happens.

Of course, check the diodes first. That is an easy job.

Since the 40 meter technical net was created many years ago, the
Sunday start time has always 20:00 GMT . Due to recent problems with
broadcast station interference, we have decided to move the net to a
new time of 4 pm Eastern. This will take effect this coming Sunday,
January 12th.

Moving the net has been a regular discussion point every winter for
several years now, but no action was ever taken. This year the signal
strength of the interfering station has been so strong, we felt it
was needed to keep the net healthy. Please make the new times on your
calendar and we hope to hear everyone this coming Sunday at the new time.

The Tuesday evening net remains unchanged and will remain on Tuesday
at 8:00 PM on 3.865 mhz.

Sunday @ 4:00 PM Eastern on 7.238 mhz +/- QRM
Tuesday @ 8:00 PM Eastern on 3.865 mhz +/- QRM

73's,
Mark, WB0IQK

I hope this helps...

Steve -

Your PS voltages don't look out of reason.

First, the relay is turned OFF by the BIAS supply, and ON by rectified AF, either from voice or SIDETONE, depending upon
MODE. So having the relay kick in without provocation usually indicates a low or loss of BIAS voltage. Same for a 'hot
PA' area, although the PA does get pretty warm just from the three big filaments. With your BIAS set at -70 VDC, the PA
stage should be cut off, even if the relay DOES kick in. Typical operating 'idle' voltage is about -62 VDC.

The '10 second' delay is the tube warm-up delay, which is typically specified as 11 seconds.

So. First thing I would do is set the BIAS as far negative as it will go. Should go to around -85 to -90 VDC. Double
check ALL the tubes to ensure that each one is in the right socket! Then pull the 6EV7 (V19). This will allow you to
work on just the receiver and find out if it's ok.

One word of advice, (too late,) if you insist on drowning a radio, verify its operation BEFORE.

Let us know what happens!

Peter -

Probably. I can't say that I've ever noticed it, but I wouldn't have paid much attention if I did! :-)

This is 'tube/valve' gear, and it gets hot. Makes sense that going from room temperature to hot would cause resonant
circuit elements to change value, requiring a minor touch-up once full operating temperature is reached.

Paul -

Absolutely first move is get the proper fuse in there!! It's a 0.75A Slo-Blo, accept no substitutes!

You can 'touch up' the Passband Tuner without a generator. Assume the BFO is on frequency, which is a reasonable
assumption unless someone has been 'fixing' it. Then follow the PB Tuner alignment instructions in Section VII, para.
'I' in the manual. Not rocket science, and you're not going to hurt anything. The S-Meter works fine as an indicator,
use AVC FAST for best response. In fact, you can do a complete 'field alignment' without anything other than the
Calibrator and S-Meter. Without a good generator, skip Para. C and D

There are three 'adjustments' for the PTO/dial setup. Start by setting the dial window so the red line is on the
fiducial marks on the panel. Then hold the MAIN TUNING knob skirt and turn the knob so that the '0' on the skirt is on
the fiducial at zerobeat of the Calibrator. Next hold the dial disk tightly and turn the MAIN TUNING until you get the
'0' on the dial exactly under the red line when the knob skirt indicates '0'. The disk has a friction clutch and WILL
slip, but can be a bit difficult to get moving when it's been in one spot for 40 years.

Date: 2014-03-01 15:35:53 UTC
From: John Lawrence
Topic: 19065 Message: 19065

I was thinking of getting an external digital display for My TR-3.
Before the purists of the group begin to jump all over me, my older eyes are not what they used to be. I need a little help to read the analog dial. I seem to to better with the digital displays on my VHF and UHF equipment.

I was looking at these http://www.electronicspecialtyproducts.com/
Does anyone have experience or knowledge of these?
I have an RV-4C and I'd like to keep this connected as well if I use the DD-103.

Does anyone have a used one for sale?

Thanks!

19066. T-4X "Asheville" - progress.

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-03-01 15:48:12 UTC
From: Steve Wedge
Topic: 19066 Message: 19066

I was getting frustrated with trying to get output on 40m. When I replaced the 12BY7, I had no output at all (the driver was weak, so I've left the new one in) on 40m. After checking the values of each trimmer/fixed cap combination and comparing against another T-4X (and finding them okay but not the same in value, which makes sense), I decided I could get in the ballpark by putting the scope probe on the buss wire at the driver output and peaking each of the 4 trimmers in succession.

I put the scope probe there, set the scope for 20V/div, AC-coupled. This was sufficient so see an RF envelope with a fairly slow sweep rate (100 us/div) and peak the trimmers. Because the scope is much more sensitive to "seeing" the peaking of the RF, I was able to get full output on 40m in about 3 minutes.

If you have a transmitter that seems to defy your attempts to get output on a single band, you may want to try this procedure. Be sure to re-peak with the probe removed, as there is a small amount of capacitive loading in the probe itself.

I hope to have this set on for the net tomorrow so I can get some audio reports - assuming I'm not out showing houses

Bob -

I'm running out of ideas.... I do not see any explanation for the purely mechanical plugging in of V10, (you say that
when you plug in V10 that the voltages on V9 (and C107) drop 'immediately', meaning before any current is drawn by V10,)
can affect the voltage on C107. I can't see any internal short paths through a defective V10 that could 'load' the
circuit node at C107. It would only take an addition 0.9 mA of current, but I can't find any 'intentional' electrical
path to support that.

It may be time to connect a meter to C107, and then probe with an INSULATED 'stick' around any wiring that might be
associated with the socket for V10 while watching for meter movement. Inserting a tube in the socket does 'stiffen' the
socket tags, possibly creating a path through adjacent wires. I realize it's a desperate move, but I just can't see
anything intentional 'electrically' that could cause this.

HaHa. I have heard enough!! I am putting it back together, it is not too bad and the last thing I want to do is break something. The dial tracking trick worked, I did hear some sort of "click", when holding the gear thing, but now it is tracking perfectly. I tweaked the passband, but I think I need to work on it a bit more. Not really sure what I am listening for. I will get the CD, this chassis is in beautiful condition (for only $150) and the radio is small enough for my BA station (replaces my HQ-170A). Thanks for all the help, I am very happy with the radio. Now gotta change those filter caps.

Paul -

The subjective 'sound' of the PB Tuner is an acquired skill. After you listen to a few dozen of them it becomes pretty
clear!! :-)

You should be able to get close by doing the following.

Rotate the Passband knob until the slugs are at their maximum travel 'out' of the box. The knob should be pointing
toward the S-Meter. Then tune in the Calibrator for zerobeat, set the Passband knob to the center of the 400 Hz line,
(between the dots,) and peak all four slugs for maximum on the S-Meter. It helps to switch to FAST AVC, and detune the
PreSelector so that the signal peaks around S-9.

That should get you very close, unless someone has been 'fixing' on it! ('Fixers' are the bane of our existence!) :-)

The dots on either end are USB and LSB, and the center between them is zerobeat. So if you tune in a CW signal for a
tone you like, you should be able to turn the PB control to one dot or the other to peak the audio (and S-Meter) level.

Subject: [DrakeRadio] TR-4C keeps going to TX

Hello All,

Here is where I start crying HELP!

Quick back story:- eBay TR-4C "...worked last time I used it. RX was working. Didn't test TX". The usual story. Came without PSU. Sourced AC3 and immediately went to install ES4AC-3 PSU upgrade kit. During installation of PSU upgrade kit found that my AC3 only had a 110VAC transformer (only one primary winding).

Tried to test TR-4C in what I thought was RX mode. With upgraded PSU running from 240 to 110 step-down transformer. No attempt was going to be made to TX as step-down transformer would not be able to supply required TX current. No attempt was made to adjust BIAS.

Result. No audio at all. Fiddled around with controls not really knowing what I was doing (Yes, I do have a manual, and Yes, I did read it prior). Still no audio. After a couple minutes with power applied the fuse 2.5A in the step-down transformer blew. There was a "burst" of RX audio. Not sure if it was before or *after* the fuse blew. Discovered to my horror that the PA cage was very warm to touch. Concluded the radio had gone into TX.

Radio was then given the "Works Clean" (Steve style :-). Yes I now know that many frown upon this practice. Hayseed electrolytic capacitor kit fitted. Lot's of other cosmetic stuff. Complete clean and re-build of PTO. Radio now looks like brand new. Tightened all under chassis screws holding tag-strips and PCB's

Second AC3 sourced. This time transformer has both primary windings. Modify AC3 for 240VAC and install ES4AC-3. Found transformer sounded like it was going into saturation at anything much over 220VAC (250VAC 50hz at wall outlet). Modified PSU with step-down auto-transformer so that supplied mains is 221VAC and also threw in a soft-start module.

Checked R42, 43, 44 - 68ohm resistors. Found all mine were at about 75ohms. Replaced them.

(Sorry this is so long).

Today was the big day. Smoke test Number-II ! Same story (grin). Well almost.

Power radio on. Mode=SSB, TX-Gain at Min. Plate & Load both Min. Nothing for about ten seconds. Then S-Meter starts to move fairly quickly towards FSD. RX audio static heard for a few seconds at this point. The relay then "clicks", audio cuts out, and I assume that I am in TX mode. I turn power off at this point.

I have measured my PSU voltages at the feed-through's under chassis. All my voltages are low because of dropping the mains supply to 221VAC. Here are my voltages under RX load:-

+650Vdc => +632Vdc
+250Vdc => +225Vdc
BIAS => -70.6 to -34Vdc (currently set -70.6)
Heater => 11.25Vac

Are my voltages causing this problem? Any advice *very* gratefully received.

73 Steve
VK2SJA

No audio.
Source 2nd AC3. Upgrade AC3

Paul:

While no expert, I did just recently successfully repaired a worn Preselector shaft for the first time.

Like you, I had some trouble figuring out how to remove the front part of the shaft. This worked for me:

REMOVE the two setscrews – just loosening did not seem to work. They have very shallow threads and will fall out easily anyways once loosened. CAREFULLY store them away and don't drop them or you'll never see them again!.

Taking a hefty pair of needle nose pliers, aggressively wiggle the vernier housing back and forth while pushing it towards the front of the radio. Eventually a ball bearing or two fell out. The shaft easily pulled out at that point.

The machined end of the shaft looks like 3/4 of an hourglass, with a shallower "slope" on the rear end. There was a groove worn by the ball bearings on that shallow slope. When I received this radio, the shaft would turn but the vernier was frozen solid so there was no speed reduction. I suspect that's why it was worn badly. Moral of the story – if your preselector is frozen up, degrease and re-grease right away!

I had a machinist duplicate the shaft out of a 1/4" drill bit – not easy to machine – but he left the machined part slightly larger than the original. I then used a file and emery to take the machined end down until it would pop into place between all 4 bearings which were placed in the housing (pre-grease to help hold them in). This took quite a while but was very successful. Yes, the bearings fell out a few times during this process, but eventually everything "fell" into place, admittedly with a pretty good shove.

So – that's what worked for me. YMMV!

Okay, Gary, I'll keep on going. It seems that if you see nothing schematically or functionally that relates V9 to V10, then it must be physical and outside the box.

Thanks for all your help and advice. It's been very informative for me. Cheers. Bob

I used to approach the Floorth Dimension in a quasi-scientific way, as a teenager. When I dropped something and couldn't find it, I'd go back to where I was when I dropped it, face the same way, and drop another of the same object -- watching carefully where it went. Surprisingly, this led to a number of finds, but I now realize my "second drop" method wasn't retrieving things from the Floorth Dimension at all -- It was merely helping to find things that bounce off it.

We all know what happens when things truly go into the Floorth Dimension -- who can deny being baffled by it? Like when things lost in the ham shack that turn up, impossibly, in the wife's sewing room and the like. Or worse, "re appear" in plain sight where you wouldn't have missed them had they been there just a moment before, like right in front of the radio!

I hope that helps further the discussion of this important topic.

And to tie it back to Drake . . . where the heck did I put my R7A?

That's what I was afraid of. Unfortunately, that's also where the RV-4C plugs in, and the Cinch connectors don't work
well with 'Y' adapters!

If the tube shield method doesn't work, John will have to add a pigtail with an RCA jack out of the back of his RV-4C
connector to tap onto the PTO signal.

Seems like it would be easiest to use the 'tube shield' method to slip over the Cathode Follower V3.

John -

I'm probably the biggest 'sticks and stones' guy on here!!! But I have absolutely no problem with an accommodation to
make it easier for someone to use the radio. My problem is with the arguments over 'who's on first', or who is 'on
frequency' +/- 1 Hz, when NONE of the combatants is actually ON that frequency!! Second is the 'everybody has to be on
a '5 kHz' mark!' WE are NOT channelized..... These are both artifacts of 'digital dials'!

Rant off, and ...

Welcome to the group, John! :-)

The FILES section has some pictures where the vernier was replaced with a Jackson Drive. If one the same way the author of the pictures did it, you won't know the Jackson drive is there. Looks very nice. I have not tried that but it does appear to be an alternative to machining new vernier inner shafts.

My hearing is quite poor but I can still find where
there is a similar pitch. Here are a couple of suggestions:
First, the best tool I've found for adjusting the slug rods
is an alligator clip. Clip it to the end of the rod. It has

enough grip to turn the slug easily and will not push or pull on it as most tweekers do. When you get it where you want it just release the clip. I get no backlash or other problems this way.
If you follow the handbook you will be OK but read carefully. When starting the knob must be centered in the slug travel. You can see the slugs at the back of the tuner. Peak all the slugs with the selectivity switch at 400 hz. Even though they should not interact I go over them a couple of times to make sure. Now, if you look at the selectivity chart in the handbook you will find that the filter does not expand symmetrically. That is why the dots and lines are not centered. After tuning up at 400 hz set the filter for 2400 hz and see what the pitch of the noise is at the ends of travel. It will NOT be the same. Adjust the knob for the center of the noise (i.e. lowest pitch) and loosen the set screws, now move the knob to the center of the 2400 hz line. Now check again to see if the pitch is the same at the dots at the ends of the line. If its slightly off adjust the knob position on the shaft again until its the same. If you can not get the same pitch go back to the beginning and re-peak at 400 hz. In my experience the peaking is quite critical. the pitch will never be exactly the same because the pass band skirts are not quite symmetrical but it should be very close. check at other bandwidths, the lowest pitch should be about in the center of each line and the pitch at the dots at the ends should be quite close.
Another suggestion; I've found that the tuning does drift a bit with temperature, not a lot but enough so that if you peak it when the set is cold it will not be quite right after it warms up fully. Let it run for perhaps half an hour before tuning it. The tuning after warm up does not seem to change significantly.
While the tuner is not as sharp as a mechanical or crystal filter its pretty good. The 400 hz position is better than the 400 hz crystal position on my RCA AR-88. The ability to shift the pass band around somewhat compensates for the lack of really sharp skirts as does the very good notch filter.

The last time the grammar police tried to come here
they fell over a dangling participle and one of the grammar
dogs got stuck in a split infinitive. They decided there was
better hunting at the local
none-of-the-news-none-of-the-time radio station.

19091. Want to buy wattmeter element

I don't give up, Gary. I just re-group!

If it's nothing electrical, it's something mechanical. First thing is to get another 6EV7 and swap it. Hope it's that simple.

If it doesn't work, then I'll take "to ground" readings on each pin and component of those 2 circuits and jiggle as I go, with and without V10.

Then I'll check solder joints.

Then I'll....

Obviously there is interaction between V9 and V10. I don't know why but I intend to find at least the cause.

I haven't ever seen you give up; I'm not either. I just appreciate your patience and the rest of the group in putting up with me. Great, great group. Bob

Its surprising what you can find. Try the following,
clean the pins on the tube using fine steel wool and make
sure no residue is left. Clean the tube socket with those
little conical brushes sold for cleaning between your teeth.
Put some contact cleaner on them and work them in the
socket.
With the power off, insert the tube and wiggle it while
looking at the bottom of the socket with a strong light.
You may find something like an unsoldered lead or a broken
terminal on the socket or a bit of solder causing an
intermittent short. For poking at wiring with the power on
I use a wooden chop stick. Watch out for modern tuning
tools because they are often conductive to prevent static
charges from building up. The can conduct enough to bite you
if you hit high voltage (from the voice of experience).
Poking at wiring with the power off is nearly as effective
since you can see if anything is loose or shorting. You can
also grab and wiggle wires with small needle-nosed pliers.
My guess is that the tube is fine. Shorted tubes can be
found with an ohm meter if you know what the pin-out is.

Tubes can and do develop shorts, but most usual is just low resistance between heater and cathode. Check your tube but I think this is something else. It helps to have a strong light and maybe magnifying glasses. Strong drugstore reading glasses work well.

19096. Re: [DrakeRadio] T-4XC problem

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-03-01 21:42:25 UTC
From: Bob Loving
Topic: 1054 Message: 19096

Garey & Bob:

Could this be similar to a problem I saw with a TR-4C (resurrected "carcass") with R135 in the VOX circuit? One value for 6FQ7/6CG7 (33k) and a different value for the 6EV7 (68k). [Garey, you then informed me that R143 was also different for the two tubes, 330k for the 'FQ7 and 680k for the 'EV7.] The problem I saw was virtually no change in the VOX dropout delay with an increase in the timing resistor, R106 (3.3M).

The characteristic curves show that the 'FQ7 requires more negative G1 bias than the 'EV7 for a given plate voltage and plate current.

The manual that came with my ePay won bid had an "errata" sheet that showed several value changes around the VOX circuit depending upon whether an 'FQ7 or an 'EV7 was used in the socket.

Are Bird and CDI elements really compatiple, electrically and
physically? I once tried to insert an element from one into a meter from
the other and it didn't fit.

Howdy Charles:

I have several Bird elements and one Coaxial Dynamics (CDI) and the CDI fits and works exactly the same as the bird elements.

Bob -

Yes, there were changes in that area, some related to the tube change (necessitated by availability of the 6EV7) and
others by the change of relay from the British relay with 15k coil (no, NOT a Lucas relay!,) to the P&B with the 2.5k coil.

The problem here however is that I cannot find ANY electrical connection between the VOX amp stages that would (or
should?) affect the voltage on C107.....

So you don't have to pore over the last few weeks worth of posts, the problem presents as V9 Plates starved for plate
voltage due to 40 VDC drop in the C107 voltage node when the 6EV7 is inserted in the socket. This is an immediate drop,
NOT delayed by tube warmup time! The drop is a little less than a mA 'extra' current through R90, a 47k resistor tied
directly to the +250 VDC bus. All of the increased drop is across R90. The relay is NOT pulled in, 6EV7 'in' or 'out'.

Bob, if I have mis-stated any of the above, please step in and correct me!

Gotcha, Garey. I just thought that there might be a connection between value changes and the problem Bob is witnessing.

Sometimes an offbeat comment proves to be worth something. In this case, not so much. I'm as befuddled as the two of you as to what is happening.

Good luck.

Nope. That's exactly how I figure it. Voltage is fine to R90, then goes haywire after that with V10 in.

So either something is wrong with the insides of the present 6EV7 or when it's in the socket something at or around the socket is shorting to something else or to ground. I view that as progress from where we started.

But i'll start with C107 voltage checks. I had intended to use my 9-pound mallet to jiggle things but an insulated stick with just have to do.

I may be bothering you and group with some meaningless data in the next few days.

My 32S-1went on a rant this afternoon saying what about me? I replied, but THIS is a Drake. Now I'm getting the silent treatment. Bob

Yes, there were changes in that area, some related to the tube change (necessitated by availability of the 6EV7) and
others by the change of relay from the British relay with 15k coil (no, NOT a Lucas relay!,) to the P&B with the 2.5k coil.

The problem here however is that I cannot find ANY electrical connection between the VOX amp stages that would (or
should?) affect the voltage on C107.....

So you don't have to pore over the last few weeks worth of posts, the problem presents as V9 Plates starved for plate
voltage due to 40 VDC drop in the C107 voltage node when the 6EV7 is inserted in the socket. This is an immediate drop,
NOT delayed by tube warmup time! The drop is a little less than a mA 'extra' current through R90, a 47k resistor tied
directly to the +250 VDC bus. All of the increased drop is across R90. The relay is NOT pulled in, 6EV7 'in' or 'out'.

You may have some adjusting to do with the coil carriage in the PBT assembly. If you don't have a VTVM, use a scope on the test point and adjust for max negative level.

If adjusting the coils doesn't change the situation, you could have a bad cap where the output of the filter goes back into the IF. I had the 0.1 metal film cap go bad and it was giving me a lot of trouble before I replaced it.

Subject: Re: [DrakeRadio] RE: R4A Preselector coils

Was listening with the radio last night after cleaning up, she sounds NICE. I think I have an alignment or other issue with the passband controls; on 4.8 kc and 2.4 kc CW signal is nice and strong, when I switch over to 1.2 kc it almost disappears, much much weaker, and 0.4 kc is even weaker. I am not worried, might be an alignment issue. The fuse in the radio is a 4 amp, THAT'S gotta go! Also PTO dial is OFF; when I slide the little red bar all the way to the left, it is STILL not on "0" when it should be. Might be a set-screw somewhere.

That passband control is wierd, all just adds "whooshiness" to my signal. But I do not have all the alignment tools needs (no decent signal generator, just an old Eico 324 and I have been told that is a horrible one).

I should have mentioned that, too, Garey. I ALWAYS make sure the set's working at least reasonably well before I wash it. Output and receive on all bands, calibrator working, meters functioning, etc.

After the cleaning, there may need to be some new parts, but I have at least established that it was a working set before it's cleaned. It makes for much easier troubleshooting afterwards if something doesn't work. Usually, they come right to life after the cleaning, but this last T-4X did not. The problem turned out to be the balanced modulator adjustment pot. Must have had some schmutz on the wiper arm.

This Tx is now sitting next to my R-4B and I had it on 15m earlier today, both CW and SSB. Interestingly, it's close enough in frequency to the R-4B that I was actually able to work transceive on SSB with it!

Subject: Re: [DrakeRadio] TR-4C keeps going to TX

Steve -

Your PS voltages don't look out of reason.

First, the relay is turned OFF by the BIAS supply, and ON by rectified AF, either from voice or SIDETONE, depending upon
MODE. So having the relay kick in without provocation usually indicates a low or loss of BIAS voltage. Same for a 'hot
PA' area, although the PA does get pretty warm just from the three big filaments. With your BIAS set at -70 VDC, the PA
stage should be cut off, even if the relay DOES kick in. Typical operating 'idle' voltage is about -62 VDC.

The '10 second' delay is the tube warm-up delay, which is typically specified as 11 seconds.

So. First thing I would do is set the BIAS as far negative as it will go. Should go to around -85 to -90 VDC. Double
check ALL the tubes to ensure that each one is in the right socket! Then pull the 6EV7 (V19). This will allow you to
work on just the receiver and find out if it's ok.

One word of advice, (too late,) if you insist on drowning a radio, verify its operation BEFORE.

Let us know what happens!

Topic: 19069 Message: 19107

I've never had to remove the slug rack, so take heart.

You may need to take off the front panel, however. I always have the front panel off when I'm doing a refurb/resto anyway, and the hole through the chassis is much larger than the hole in the panel, allowing you more room to move things around.

The Jackson Drive assembly - including the front shaft, which is attached permanently - can move toward the front of the set and lifts out of the hole in the chassis. You may need to crimp the bottom retaining tab that positions the drive to the chassis, as they're usually flattened when installed to hold them in place. The front shaft doesn't come off the drive assembly. There is enough slop in the whole thing, when loosened, to get it off the slug rack shaft.

Don't forget that the whole thing works by having a pre-load, pressing toward the front. Get it so that there's some pressure in that direction when reinstalling and you should be okay. It can be a little finicky. Once you know it's working right, you can re-flatten the tab under the chassis again.

I need to take some pics of the next one I do, as it's easier to do than it is to describe it.

Paul -

Steve is our vernier expert!.. I seem to recall you have to remove the slug rack to get it OUT of the radio.

There is a 'fix' for certain conditions that consists of a spacer to force the smaller, center shaft further forward to
allow the balls to ride 'outside' the groove. It's on my CDs, and I'll send you the file.

The vernier assembly itself is 'crimped' together, and not designed to be 'repaired'.

All:

Evidently there is more than one style of preselector shaft and vernier housing out there. The method I described worked for an SPR-4 of mid-run vintage, but the photos of an R-4A shown here;

http://www.k4lrg.org/Projects/Magic_of_Boatanchors/index.html

show a shaft without an “hourglass-shaped” machined end, but one with a more “square-cut” thinner diameter at the ball race. The idea is pretty much the same however. The other difference on the R-4A appears to be a rear cover for the bearing race, if I am interpreting the items in the picture correctly. The SPR-4 I repaired had no bearing race cover on the rear-facing side, leaving the bearings to be somewhat visible from the rear. Although difficult to be sure, I am almost certain the 4 bearings in the SPR-4 were quite a bit larger than those shown in the R-4A pics.

Unfortunately, K4LRG does not describe removal of the preselector.

Indeed, as Steve has stated, removal of the front panel affords one much extra space for working on these. This is done as a matter of course on any 4-line refurb done here.

As usual, YMMV!

19110. Re: [DrakeRadio] TR-4C keeps going to TX

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-03-02 03:56:19 UTC
From: Steve VK2SJA
Topic: 18933 Message: 19110

Garey,

I'm shocked! Shocked I say. That you would think for even one moment that this young (~=50) Aussie bush ranger would rip into a rig without first verifying it's operational state! I did *verify* it. It wasn't working. So THEN I washed it. :D LOL.

Sorry, All jokes aside I do get the point. I hereby faithfully promise that I'll always "fix before clean" in future.

The RX worked beautifully with V19 pulled. Thanks for the pointer. So then I got out the circuit diagram and your indispensable service guide and went hunting for my missing BIAS voltage.

I found it. I fixed it. I caused it.

Forgot to mention that I replaced the 1/4" phono jack with a NOS S230 socket. I like to try and keep things as original as possible. The wire controlling PTT that goes from the tip of the S230 to the junction of R105, R108 & R142. I had inadvertently soldered this wire to the ground lug of the S230 socket. So of course the radio was in TX!!

Along the way discovered that R106 3.3M was closer to 25.1M. So I replaced it.

I ended up having to replace the wire running from the S230 socket to R105. Looking around in my junk box the closest thing I had to the original wire was some solid core Cat5e wire. But that nice new blue wire and small yellow cable tie just looks so out of place :-(

Anyone got a suggestion for where I might obtain some suitable "Drake" looking wire?

Time to take a lunch break and then on to the alignments. Still to find out if the TX side of things works.

I'll let you know how I get on.

Thanks All!

73, Steve

Agreed, the blue dial & meter, and red indicators make the TR-4 a pretty sight when the lights are out. I'll bet the glow of the tubes with the cover off really spiffed up the look. I did that just the other night for the first time :) 73, Scott WA9WFA

I have a theory that things that run by heat all seem alive. Tube radios and steam locomotives for instance. We know there are electrons running around in the solid state stuff but they are like ants, just following some mysterious plan, but tubes glow and are hot like us. You can visualize the little electrons streaming around in the tubes doing stuff.
The first time I saw a Drake rig (new, belonged to my brother) I thought the blue dials looked phosphorescent.

From: <w9dz@...>
Topic: 18936 Message: 19117

If the 2.3 filter was bad I believe it would affect transmit too as that filter is used when transmitting any mode.

I just removed the filter board and proceeded to check the diodes. When I went to check CR-904 which is a shunt diode, it's missing! The leads have been cut/sheared off even with the top of the board. Would this have been some kind of mod/production change or should the diode be in place no matter what?

Thanks

Two I am aware of..

The 729 SRD was a Drake branded EV-729SR that was offered with early Drake 4-line rigs though am not aware of exact dates it was available.

Later on the Drake 7075 with moulded right angled .210" mic plug suited the TR-series transceivers and B-line very well as they had side mounted mic jacks. Nice mic for the C-line too! Not sure who the manufacturer was but guessing it was Astatic.

The Turner 444 works well with the 4-line.

The later Drake 7077 with 4 pin mic connector was offered for the 5 and 7 line.

The 7075 is a Turner, and I believe it uses the same ceramic element as the Turner +3 amplified mic. The design is the same as the +3 series except for the hole for mounting the gain pot in the Turner. The +3 is a very good sounding mic on my TR-7, as tested with along with a variety of mics during QSOs with friends who know my voice.

I also have an EV 729, and it's "brother" the 927, and I'm told that they also sound very good. The 729 has a ceramic element, and the 927 is the same mic with a crystal element. I was surprised that the 927, as old as it is, worked at all....

The 444 is also an excellent sounding mic, but has a somewhat different "character" due to it's dynamic element.

The 7077 was a dynamic mic manufactured by Astatic. I have one of those too. I don't use it much because it was at the bottom of the pack in my test sessions. Not that it isn't a good sounding mic, it just wasn't preferred over any of the others I've tried. I've considered trying to swap it to someone for a 7075. It seems silly to keep it just because it matches my 7-line.

Long ago on a beautiful day in Austin, Texas, I was sitting
in my driveway testing a big box of tubes. A young lady
student came by- she was selling something- don't remember
what it was. She asked:
"What are those?"
"Vacuum electron tubes. They're used in antique radios."
"Aren't those the things that have red fire in them
when you turn them on?"
"Yes, you could say that."
"That is so cool....."

Nice memory.

Steve -

Cool! Glad it was an easy fix... At least you 'verified' it didn't work..... :-)

Service, restoration, repair, are ALL 'divide and conquer' exercises.

With that R106 in there you would have waited a long time for the VOX to drop out after each transmission.... :-)

Fortunately, I don't think anyone else was foolish enough to use that wire. Possibly from a donor unit, might post a
'want'.

Onward and upward! :-)

I know of no mod, (or reason,) to remove CR904, unless it was shorted!! Perhaps one of our TR-7 experts knows of such a
mod.

I can only see that it would allow some signal through the 2.3 filter even when any other filter was selected. I don't
see how that would affect your specific problem though. Sure not a good sign though, 'someone' has been 'fixing'!!! :-)

From: Steve Wedge
Topic: 19127 Message: 19127

I'm ready to start another project (and whittle down my pile some).

T-4X, s/n 13610 (R) - a fairly late number.

Nice chassis with a few spots -nice & shiny. Small abrasion near the meter window, some chips off the top cover's edge that have been touched up. Band switch detents are not as sharp as they should be but it does detent.

Strong finals - can get over 100W out on 15 and about 100 on 10. Works as it should. HV can cap was bypassed and a discrete electrolytic sits underneath doing the job now.

I've got some nice photos for those who are interested.

$200 + shipping.

All group members are welcome to post on this message board, so for those that have questions please don't be shy and for those that have answers, please feel free to give advice to others. No one is 'keeping score' (I hope!)

PLEASE use the 'Reply All' function of your e-mail client so replies are posted to the list. A 'Reply' to the original poster ONLY, deprives the rest from seeing an answer, AND greatly diminishes the value of the List archives.

For those of you that have not introduced yourself we welcome you to do so and please feel free to upload your station pictures to the photos section of our group's home page, as well as links to Drake information or your homepage.

Just a word of advice for R-7 / TR-7 owners 'with a problem'. I estimate that 90% of 'failures' in these units are caused by minor oxidation of a switch, the card and/or cable connectors. Whether it's a problem that just shows up at turn-on, -OR-, after the unit has been unused for a while, DeoxIT'ing switches and just re-seating cards and connectors will often get it going again. If not, you know where we are!

73, Garey - K4OAH

I'm using one on my R4C/T4XB combo set up for transceiver mode. I'm using a "Y" connector on the INJ jack - works great.
I checked and set the read out against my Icom R70 HF receiver for accuracy.

Since they are programmable I've also used it on my Swan 250. They have five different memory settings , so I could set it up for all the receivers in my shack if I wanted to mess with re-connections or switching set ups.

I was thinking of getting an external digital
display for My TR-3.Before the purists of the
group begin to jump all over me, my older eyes are not what
they used to be. I need a little help to read the analog
dial. I seem to to better with the digital displays on my
VHF and UHF equipment.

I was looking at these http://www.electronicspecialtyproducts.com/ Does
anyone have experience or knowledge of these?I
have an RV-4C and I'd like to keep this connected as
well if I use the DD-103.

Does anyone have a used one for sale?
Thanks!

Thanks Peter for the Drake microphone info. I've seen the Electrovoice 729 before as I sold one last Fall. I didn't know Drake had branded versions of that. I went out on GOOGLE and searched but couldn't come up with a picture of a Drake branded version. From the WB4HFN website I was able to bring up several 70's Drake catalogs and see the Drake 7075. I've never seen that before. It's funny that I sold a similar looking microphone last Fall, Turner branded, that looked similar, same base, except that the mic head looked just like the Collins/Turner SM280. Now that I think about it, the seller mentioned having a Drake microphone. I'll ping him to see if he's selling it too. He may have decided to keep it along with the L-4B.

Ok on the Shure 444, sure I know those mics. I sold one last Fall as well. I'm using my D-104 right now and it sounds fine.

Well, I jiggled the pins of V9 and V10. Suddenly got tone in TUNE and SPOT, and got my usual 100-120 watts output.
Yeah! Tried unsuccesfully to replicate the non-Tone situation but it worked fine from then on.

So I switched to 20 to work a few contesters and the 6JB6 nearest the back corner flashed a bright blue inside, issued a quarter-second of smoke, and blew a fuse. Tried another AC-4 and it blew a fuse.

Pulled the tube and tested for shorts and emission. Normal shorts as indicated on my tube tester chart bit zero emission, Pulled the other final. Normal shorts and full emission.

Visibly inspected the area and measured a little. Each side looked and measured the same.

Hopefully the advice here is short and clear, as in tube blew, get another.

And it sounded so good and normal again! Growl. Bob

Bob -

Well, you found it! :-) It's possible one of the finals wasn't working well and the other overloaded trying to reach
'full power'.

Yes, once you get the correct Plate voltage to V9, all those problems WILL disappear, they ARE all related. (Except for
the PA!)

I wouldn't risk any more finals until you find and FIX the problem in the V9, V10 area. At least you now KNOW it's
'mechanical', not electrical. We went over the hardware 'loosen/tighten' process pretty early. Check to make sure
there isn't a wire crunched under a tube socket or terminal strip. Or a sharp edge of something 'cold flowing' through
wire insulation. Leave V10 out of the socket, and the PA tubes too. Then just dig into that V9/V10 area while
monitoring the voltage on C107.

Is to a means of grabbing the frequency before the net starts or is it a way for the net controllers and others in the hierarchy to chit chat and tell each other what radio they are using? I am not this to PO anyone or to start a fight, it just seems that the time could be better served to answers Drake technical questions that don't get answered during the nets time slot. Or perhaps check people in right then so they don't have to kill better part of 20 minutes during the net itself. Then there is the fact that no one has explained what the so called pre-net is all about.

in a nut shell?

Hold onto the frequency before the net starts.

It's quite possible that someone could call cq three minutes before net
time and end up in a long winded qso. And not qsy when asked by net control.

Think of it as the guys milling about before the club meeting.

As far as practicality, it's good that they wait until 4 EST: that broadcast QRM is incredibly nasty before 4, anyway.

Evan and others had mentioned something today on the Drake Technical Net that I'd been thinking about for some time. That is, can we substitute other tubes for the 12AX7's that are in our rigs?

The 12AX7's price has escalated in the open market due to tube audio fans' demand for them. I can see a day when they command the same price as a 6HS6 simply due to the placement on the supply/demand/cost curve.

I know that the compatible tubes have different gain characteristics, but has anyone played with using 12AU7's or 12AT7's?

I can remember seeing 12AU7's used in audio circuits in other equipment; 12AT7's were used in Tektronix vertical amplifiers quite a bit, in the pre-585 period scopes, and were used up to 25 MHz.

I know that the 12AX7 used in the transmitters has one side that's an audio amp and the other side, that's mainly just a switch. I'm sure that there are biasing issues with this side that could impact the audio response of the rig if the resting voltages aren't changed first.

I have some of these alternate tubes in a box and I'll do some experimenting, but I'm mainly looking for any feedback from anyone else who has tried either of these substitutions. Up until recently, the 12AX7 has been cheap and readily available. That is changing, and I'd like to be prepared (sort of like the 6AH6 as an alternative to the 6HS6).

12ax7's are still plenty available and cheap, if you look for them (not on eBay). I bought a used Telefunken 11ax7 at a hamfest today for just $3.

Not to mention how CHEEP the china and Russian ones are. IMO this is no cause for alarm forcing the re-designing of our precious Drake circuitry.

19150. Passband tuning circuit board

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-03-03 02:04:23 UTC
From: <rochep@...>
Topic: 19150 Message: 19150

I am still having a dickens of a time getting my passband tuning right. Question #1. When the manual says to align the passband slugs "When the slugs are nearest the REAR of the receiver, the PASSBAND knob should be pointing left (as viewed from the front)". What does "nearest the rear of the receiver" mean, are the slugs sticking OUT of the assembly (toward the antenna jack) or are they retracted INTO the assembly (so they are actually pushed toward the front of the set). Sorry for the stupid question; I am a scientist and read things literally.

On my circuit board there is ONE screw (lower left looking from the front) holding the passband circuit board to the big square assembly-thing. When I turn the passband tuning knob, this circuit board actually moves forward and backward. Is this normal for the circuit board to move while I turn the passband knob? When I TIGHTEN this screw, the circuit board does not move, but the passband tuning knob just spins around ((I think it is not working). I have ordered Garey's CD, but wonder if something is amiss here (is it SUPPOSED to be a single screw that is REALLY loose?).

paul

Yes. The slug rack moves. It is set so that when the slugs are sticking out the back at max, the pointer should be at 9 o'clock.

Steve Wedge, W1ES/4

Scott:

Glad you're enjoying the "new" rig! Just beware – 4 –lines multiply at night like rabbits! So do 7-lines!

I have used the EV–729SR and sounds fine. I don't have one of the Drake branded versions so can't send you a pic, but I am sure there are others on here that could do that.

The 7075, as Jim confirmed, is manufactured by Turner, and works really well on any of the 3 & 4-lines (and 6-line!). Easy to use too with its moulded right angle .210" plug.

I have also used the Turner +3 and it gets great reports on the audio as long as you watch the drive. The battery tends to run down quickly so I usually pull it when I am away from the shack for any length of time.

I've used amplified (very carefully!) and unamplified D-104's as well but usually save them for the Cedar Rapids boxes nowadays. I use a Shure 55 on the Drake TR-4310 – probably not the best choice but it sure looks cool!

I am using 7077's (made by Astatic) on the 5 and 7 line gear. Seem to work well though can't say I have had any "outstanding audio" comments. Mind you they haven't been in transmit mode a lot lately – just not home enough in winter.

I'd forgotten about the hand mike that Jim, N5KY, mentioned. I had remembered the 7073 hand mic for the 7-line but not the 7072. I have a small Shure hand mike with 4 pin plug that came with some 7-line gear years ago and it works well. Don't recall the model # – it's buried in a box at the moment.

Just got home from the ski hill so have to go dig up that QST ad pic of Ray Grenier, K9KHW, so I can get it scanned tomorrow.

Thanks Peter for the Drake microphone info. I've seen the Electrovoice 729 before as I sold one last Fall. I didn't know Drake had branded versions of that. I went out on GOOGLE and searched but couldn't come up with a picture of a Drake branded version. From the WB4HFN website I was able to bring up several 70's Drake catalogs and see the Drake 7075. I've never seen that before. It's funny that I sold a similar looking microphone last Fall, Turner branded, that looked similar, same base, except that the mic head looked just like the Collins/Turner SM280. Now that I think about it, the seller mentioned having a Drake

microphone. I'll ping him to see if he's selling it too. He may have decided to keep it along with the L-4B.

Ok on the Shure 444, sure I know those mics. I sold one last Fall as well. I'm using my D-104 right now and it sounds fine.

Chris:
>>> I bought a used Telefunken 11ax7 at a hamfest today for just $3.

No wonder you got it so cheap! You're gonna run hot with that 11 volt filament!!!!

I'd be really careful about the Chinese and Russian tubes. I recently "fixed" a Fender Hot Rod Deluxe guitar amp for someone that had spent $200 buying a new set of tubes for it – one of the new 12AX7's in the Channel 1 preamp had a dead triode section – and I found that all of the Russian miniature tubes seemed to have slightly smaller pins that almost allowed the tubes to fall out of their sockets. They are upside down in that amp and Fender used a foam block to hold them in place. It's gone back to the owner now or I would put the micrometer on those pins and compare to my NOS.

The 12AX7's price has escalated in the open market due to tube audio fans' demand for them. I can see a day when they command the same price as a 6HS6 simply due to the placement on the supply/demand/cost curve.

I know that the compatible tubes have different gain characteristics, but has anyone played with using 12AU7's or 12AT7's?

I can remember seeing 12AU7's used in audio circuits in other equipment; 12AT7's were used in Tektronix vertical amplifiers quite a bit, in the pre-585 period scopes, and were used up to 25 MHz.

I know that the 12AX7 used in the transmitters has one side that's an audio amp and the other side, that's mainly just a switch. I'm sure that there are biasing issues with this side that could impact the audio response of the rig if the resting voltages aren't changed first.

I have some of these alternate tubes in a box and I'll do some experimenting, but I'm mainly looking for any feedback from anyone else who has tried either of these substitutions. Up until recently, the 12AX7 has been cheap and readily available. That is changing, and I'd like to be prepared (sort of like the 6AH6 as an alternative to the 6HS6).

Steve -

Not very well..... The 12AX7 is a High u triode, The T is a High u triode (not as) and the U is a Medium u.

The other pertinent facts are
Amp - u
T - 60 - 15k
U - 20 - 3k
X - 100 - 80k

There's a reason they are used 'everywhere'! :-) Add in VERY low Hum and Noise specs. They're used in the T-4X(any)
transmitters as MIC amps, a CAR OSC and an ALC amp. Not trivial circuit changes. Best bet is to pick them up where you
find them before they go even higher.

You 'could' build an adapter that would hold two 6AV6s!

Save the 12AU7 and 12AT7 for your VTVM.

I recently purchased some new production Russian 12AX7 tubes very reasonably. For ham radio use they should be just fine. In a recording studio that may be another story.

Paul -

Yes, the board moves a little to accommodate the movement of the switch wafer. The center shaft is the Passband
control, and is 1/8" in diameter. There is a small fiber shim inside the knob that is 1/8" id and 1/4" od. It is slit
longitudinally to allow it to compress on the smaller shaft when the knob setscrew is tightened. The insert MUST be in
the knob with the slit at right angles to the setscrew to allow it to compress. If it's NOT this way you can tighten
the setscrew until the knob cracks and it will still slip!

Yes, the slugs are confusing. You want to turn the Passband knob so the slugs extend as far OUT of the housing, away
from the front panel, as possible. Do NOT adjust the center screw on the back panel of the housing, yet.

Steve and others,

As a new ham, I often switched to the 12AT7 or 12AU7 from the 12AX7 due to reduced gain and thus less prone to hum and stray pickup. Having too much gain is not always a good thing and can lead to undesirable results. A relevant concern is the circuit design though. If gain is an issue, then yes, by all means use a 12AX7 if that is the preferred alternative, cost aside.

Wow - lots of input. That's why I love posting stuff like this to this group.

Of course, I was too lazy to get out the receiving tube manual (where the heck is it, anyway?). I did not, however, think about the hum issues - a real issue when you're talking about mic amps.

I do still have enough good 12AX7's; I'm merely trying to plan against the day when they'll be harder to come by.

Re the pair of 6AV6's: I think I'd hide a couple of FETs under the chassis before I'd punch another hole in it!

>I have also used the Turner +3 and it gets great reports on the audio as long as you watch the drive. The battery tends to run down quickly so I usually pull it when I am away from the shack for any length of time.

There might be a problem there. I think I've changed the battery in my +3 once since I started using it. But I don't remember for sure if I did or not. Check the wiring on the leaf switch, it should be turning the battery off when unkeyed.

As a general rule I detest amplified mics. They are usually not necessary and can create more problems than they solve.* There is not a D-104 T-UGx stand in the house here that still has the amplifier connected. The unique thing about the Turner +3 is it has a real compression amp. It can be of some benefit with radios that don't have any "processing" built in.

(*Unless the system is DESIGNED to require a premplified mic.)

19161. TR-4C PA Neutralization

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-03-03 03:32:36 UTC
From: Steve VK2SJA
Topic: 18933 Message: 19161

Hi Chaps,

Now that my *new* TR-4C is "glowing" and "singing" again. I'm looking towards doing the alignments. In particular the PA Neutralization. I've been scouring the archives. And it appears that if you already have the rig opened up for surgery, that the "cold screen-grid" approach is actually the easiest method. So long as your careful about safety (always) and treat gently the feed-through cap so as not to break it.

I've put together my own "procedure" for doing this by reading multiple previous posts to this group. Can you guys in the "know" have a read of my procedure below, peppered with questions, and let me know if I'm about to do anything stupid. i.e. have I missed something obvious in my ignorance.

Remember that "I know nothing about tubes/valves"!!

Thanks!

73, Steve.

----- TR-4C PA tube neutralization procedure: -----

Cold screen-grid method:-

1a. Does the IF neutralization procedure need to be done *before* the PA neutralization or are they completely independent adjustments?

1. Properly tune the radio transmitter for output on 28.8Mhz (plate dipped correctly).
Why this frequency? Just because it is pretty high
and available from one of the stock crystals?
Is this just to get you "close" to the final adjustment point?
Is this step really required?
What if the radio runs away in oscillation while your trying
to tune properly for this frequency? Drop to a lower band say 15m and
try again there?
Where should we adjust/leave the XTMR GAIN control at this point? 0.2A on
plate meter or does it not matter because we are disconnecting the
screen-grid supply?
2. Disconnect power supply from rig altogether!!! ***ZAPPO SHOCKO***
3. Disconnect the +250VDC screen-grid supply at the bulk head feed through.
**Be very careful with the feed-through caps. They can break easy enough
if your rough with them.**
Which side of the feed-through is best to disconnect?
4. Very carefully *insulate* disconnected +250VDC wire so that it can't
harm you or the rig! ***ZAPPO SHOCKO***
5. Connect rig to dummy-load via modified PL259 "T-piece" aka RF-Sniffer

(centre pin ground down).
6. Connect scope with 1:1 probe to RF-Sniffer port on modified PL259
"T-piece".
Can you use a RF power meter here instead?
7. Using a *PLASTIC* non-conductive adjustment tool only! Adjust C76 for
dip (minimum RF output on scope). ***ZAPPO SHOCKO***
C76 is normally hot with +250VDC!
Is C76 still hot after disconnection of +250VDC at the feed-through?
Aside from the critical safety issue does a metallic adjustment tool
throw out the adjustment point? Perhaps not. It's a capacitor not an
inductor.
8. Disconnect power supply from rig altogether!!! ***ZAPPO SHOCKO***
9. Re-connect the +250VDC screen-grid supply at the bulk head feed through.
10. Job done.
What (if any) additional sanity-check should be done at this point?
Checked the dip vs. max output on 10m?

19163. Re: [DrakeRadio] What is the purpose of the Drake Pre-net on 40 meters

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-03-03 03:52:01 UTC
From: Evan Rolek
Topic: 19140 Message: 19163

Fellow Drake Enthusiasts,

To my knowledge, there is no defined, official purpose for the pre-net before the Drake Technical Net. Just observing the QSOs in the time frame before the net, it appears to be a friendly, informal discussion of various topics, most being related to Drake ham equipment. Too, it serves as an informal "heads up" to others tuning across the band that there is a net soon to follow that emphasizes helping people with issues related to Drake equipment. Sometimes technical issues are addressed during the pre-net and at other times they are delayed until the formal net due to the availability of the respective experts. It does help too for logging in stations before the formal net and thus reduces the size of some of the pileups, hi hi.

The fact that the pre-net has not been "defined" suggests that there is no formal, required agenda. To me it is just a group of Drake enthusiasts getting together for some enjoyable conversation. I've often listened to that frequency in the background and will sometimes hear a person say "Is the frequency in use?" If convenient, I respond and say that no, the frequency is not in use, indicate what time a net starts (not that we own the frequency or time slot), and then invite them to join the net; this is in stark contrast to certain other "dead" frequencies that result in a response akin to "Nobody is talking but we're holding the frequency in case somebody from the XYZ organization wants to use it". So no, I would not say anybody is trying to grab the frequency. There have been times where the foreign broadcast station occupies the frequency, when it is being used by hams in an ongoing QSO, etc. and so we accommodate the situation by going to an alternate frequency.

Finally, if anybody has constructive criticism, suggestions, questions, etc. they should feel free to contact any of the net controllers and make their thoughts known.

Have a great week, stay warm, stay dry. Spring will eventually get here so do your outside antenna work now before you get bogged down with yard work, hi hi.

73,

Evan, K9SQG

Subject: [DrakeRadio] What is the purpose of the Drake Pre-net on 40 meters

Is to a means of grabbing the frequency before the net starts or is it a way for the net controllers and others in the hierarchy to chit chat and tell each other what radio they are using? I am not this to PO anyone or to start a fight, it just seems that the time could be better served to answers Drake technical questions that don't get answered during the nets time slot. Or perhaps check people in right then so they don't have to kill better part of 20 minutes during the net itself. Then there is the fact that no one has explained what the so called pre-net is all about.

Topic: 19145 Message: 19165

Hi Steve,
The ECC83 or 12AX7 always have been very popular with valve audio amplifier manufacturers and with the resurgence of interest in valve amps are back in demand.
The main difference between this and the ECC81 or ECC82 (12AU7/12AT7) is gain.

The ECC83 is a high gain double triode whereas the other two are lower gain.
That said it depends on the circuit and you may find that the lower gain ones are adequate.
Here in the UK, they are plentiful at our Radio Rallies/Hamfests and there are still good ones available for a £1 or so if you strike lucky.
Valve oscilloscopes used them, VVM's used them, valve tape recorders were bound to have at least one in.

The Plus side is there are a lot of pin equivalents out there but I would avoid the Chinese ones and eBay where the prices are silly. the ECC83 is of course the British one, the 12AX7 the American equivalent.
Mullard or Brimar are consistantly good but beware folks pulling low emission valves and selling them.

Russian tubes are usually high quality and can be relied upon.

Good Luck in your search. If you find 'em buy a few!

Regards

Ian

Subject: [DrakeRadio] Using alternatives to 12AX7's

Evan and others had mentioned something today on the
Drake Technical Net that I'd been thinking about for some time. That is,
can we substitute other tubes for the 12AX7's that are in our rigs?

The 12AX7's price has escalated in the open market due
to tube audio fans' demand for them. I can see a day when they command the
same price as a 6HS6 simply due to the placement on the supply/demand/cost
curve.

I know that the compatible tubes have different gain
characteristics, but has anyone played with using 12AU7's or
12AT7's?

I can remember seeing 12AU7's used in audio circuits in
other equipment; 12AT7's were used in Tektronix vertical amplifiers quite a bit,

in the pre-585 period scopes, and were used up to 25 MHz.

I know that the 12AX7 used in the transmitters has one
side that's an audio amp and the other side, that's mainly just a
switch. I'm sure that there are biasing issues with this side that
could impact the audio response of the rig if the resting voltages aren't
changed first.

I have some of these alternate tubes in a box and
I'll do some experimenting, but I'm mainly looking for any feedback from anyone
else who has tried either of these substitutions. Up until recently, the
12AX7 has been cheap and readily available. That is changing, and I'd like
to be prepared (sort of like the 6AH6 as an alternative to the
6HS6).

On the TR-3 and 4, you can disconnect the wire on the side outside the PA compartment, which is easier that removing and possibly breaking the RF choke.

I've found no change in the scope display when using a metal screwdriver blade.

Yes, do disconnect the ps before going in. Be sure the other caps within are also discharged.

Steve -

1a. Totally unrelated.

1. Start with C76 about mid-range. You won't get oscillation unless there is some other problem. Turn GAIN to
minimum. The higher the frequency, the sharper the adjustment point. Not critical. Just the higher, the more accurate
the adjustment.

2. Yep!

3. I prefer 'outside'. 'INside' is 'part of the circuit' RF wise.

4. Yes.

5. Leave dummy load connected.

6. NO power here.

7. You are adjusting a very small capacitor. Metal tool ADDS capacitance. Fiber or plastic. No 'anti-static'.
Adjust for minimum!

8. Yes.

9. Yes.

10. Wouldn't hurt just for confirmation, not necessary.

19171. Re: [DrakeRadio] Passband tuning circuit board

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-03-03 14:30:35 UTC
From: Steve Wedge
Topic: 19150 Message: 19171

The screw in the back changes the central position of the slug rack. The adjustment of the passband should be such that you have the same response at either sideband.

After peaking the slugs (which sets them all to the same frequency) you may need to adjust the overall position of the entire rack. The screw does this and is usually set by ear, though you could use more sophisticated methods.

So, basically, you set the position of the knob, relative to the shaft, by backing the slugs out fully, move the pbt to centre and peak the individual slugs, then adjust the actual response, relative to position of the knob.

HTH,

Steve Wedge, W1ES/4

Paul -

If no screw, only the wires would prevent the board from turning WITH the switch frame, rotating the board instead of
changing the switch setting. Just enough to keep it from turning with the switch frame! :-)

Snow is not such a bad thing when you spend 4 days/week at a ski hill!

Tough skiing all that powder! Tough to get any Drake projects (or any other for that matter) done, but I'll worry about that in 6 weeks.

One thing about posting Ray's pic – I have e-mailed him (hopefully) at West Mountain Radio to ask his permission to post that pic. Got thinking about that last night as I lay awake with a sore throat and earache half the night. I felt it was the right thing to do before posting it here. With luck my e-mail will reach him and we will get his permission.

Topic: 19150 Message: 19180

Thanks for the info, I still have work to do. With the passband pointer to the left there is a "whoosh" sound, tuning THROUGH the center position I loose the whoosh, and then tuning to the right I get the whoosh again. That sounds right. About the same pitch at 9 o'clock and 3 o'clock. I don't like the tone of the whoosh, so far I like to tone when centered (but I suspect it is not set correctely).

What is strange is that on 20 meters (USB) the talking is intelligible only when set to the U position (I guess that makes sense). But on 40 meters and 80 meters (LSB) the talking is intelligible when set to the L position OR the U position. This clearly does not seem right.

I'll get there, I am able to hear and work DX, that is the point.

Joe to be on the safe side I think you should go for a pass port. One never can tell when some passenger decides to high jack the aircraft, pilots are even doing it now. Remember 9 - 11 when us good hearted Canadians allowed the planes that were destined to land in east coast American airports, they all ended up landing in Saint Johns NFLD and Moncton N.B. You no doubt know that you used to be able to use your birth certificate or drivers license, but not any more.

From: Garey Barrell
Topic: 19150 Message: 19182

Paul -

If you tune in the Calibrator, in the 2.4 kHz B/W, and tune to zerobeat, the S-Meter should peak at the center of the
line between USB and LSB with 2.4 at the end! If you tune in an SSB signal, you should hear USB or LSB on the dot's at
either end of the 2.4 line,

Joe -

There are no 900 MHz repeaters in the area. There is some 220 activity, and a repeater, but it is down more than it is up. KL6M operates on 220 simplex fairly often.

Assuming you fly from a USA airport to Anchorage, no passport will be needed.

One time I was on a flight from Minneapolis to Anchorage that had to stop in Edmonton, Canada for additional fuel, the passengers were not permitted to leave the aircraft, so passports were not an issue. The reason we had to stop was that it was so hot in Minneapolis (100+ degrees) that the plane could not take on enough fuel to make a non-stop trip. This was because the warm air meant an extended take-off run, so the plane had to be lighter than normal. (cool air provides much more lift than warm air)

If you plan to have time for some sight-seeing, I can suggest a couple of great day-trips.

From: docbrent
Topic: 18933 Message: 19184

On Jim's recommendation, I too am using a Turner +3 on my TR-7. Audio reports are invariably very good. Sometimes embarrassingly effusive.

I have to keep the mic gain down just below 9 o'clock. When I use the my Drake speech compressor, I can only go to about 3db before it gets harsh, but I haven't really tested it out thoroughly. That was going by the reports of a local, not a distant station pulling me out of the noise.

Just one battery for a couple of years now, by the way.

I also have a Turner Super Sidekick, obtained before the +3. I haven't used it much. I had one very negative report -- indeed, it was more of a lecture, from someone who hated the fact I was using a CB mic on a ham radio. Maybe he'd have sung a different tune if I told him it was a Heil or something more "dignified."

Maybe time for a side-by-side. The Super Side Kick is a better match to the TR-7 colour scheme, if you can overlook the blingy chrome at the mouth piece.

I've looked high and low for a +3B. I had one before, but sold it with my old TS-520. It was that mic that cinched the deal, by the way, when I was demo-ing the radio. It made a "holy cow" improvement over the stock MC-50.

I'm sure it was these microphones that inspired the Byrds, in their classic rendition of the Pete Seger song . . . (everyone sing along now) "To everything, Turner, Turner, Turner."

>I have also used the Turner +3 and it gets great reports on the audio as long as you watch the drive. The battery tends to run down quickly so I usually pull it when I am away from the shack for any length of time.

There might be a problem there. I think I've changed the battery in my +3 once since I started using it. But I don't remember for sure if I did or not. Check the wiring on the leaf switch, it should be turning the battery off when unkeyed.

As a general rule I detest amplified mics. They are usually not necessary and can create more problems than they solve.* There is not a D-104 T-UGx stand in the house here that still has the amplifier connected. The unique thing about the Turner +3 is it has a real compression amp. It can be of some benefit with radios that don't have any "processing" built in.

(*Unless the system is DESIGNED to require a premplified mic.)

My wife got the paper passport..I only applied for the card version....What was interesting is that we spent 5 weeks in B.C. this past summer. We borrowed a float plane (Based in B.C.) and flew up to this little, remote lake where we honeymooned 40 years ago. (Only way in is to hike or fly..no roads anywhere near.) and spent 2 weeks there, before returning to Vancouver area, where we spent another 3 weeks sightseeing..the Island, and places of interest in and around Vancouver. (My favorite, and has been since the first time I was there, 40 years ago, is the Bloedel Conservatory in Queen Elizabeth Park. Then its down into the gardens for a delightful 5 hour stroll..well for me.) Not once, while in B.C. were we ever asked for our Passports...only when entering Canada and entering back into the United States at Blaine, Washington. In fact we weren't ever asked for an id when we refueled the plane..they just took our credit card, ran it, and said thank-you! Go figger!

Oh well..BTW..if a plane had to make some sort of emergency landing in Canada, they wouldn't push the passport issue...just make us stay in the terminal, or in the plane (UGH!) But still...I guess I need to go down to the Post Office and apply for the paper passport, then not worry about anything.

Joe to be on the safe side I think you should go for a pass port. One never can tell when some passenger decides to high jack the aircraft, pilots are even doing it now. Remember 9 - 11 when us good hearted Canadians allowed the planes that were destined to land in east coast American airports, they all ended up landing in Saint Johns NFLD and Moncton N.B. You no doubt know that you used to be able to use your birth certificate or drivers license, but not any more.

Yup...called density altitude...big problem for small plans here in Reno, where I have seen D.A. as high as 12,000 feet (At airport elevation of 5500 feet.) Phoenix's commercial airport has BIG issues in the summer with the commercial jets being too heavy for the high temps and density altitude. Even seen where they all have been grounded due to the H.D. figures.

Thanks..I will leave the 900 radio home (Unless I opt to bring the new toy..the Alinco DJ-G29, which is a 220/900 dual bander)...Thinking about it, probably not..the TH-F6a is smaller and lighter and has more power...5 watts as opposed to 3 watts on the Alinco.

I will keep your email handy...as it gets closer to travel time, I will ask you about car rentals, and places to see, that are NOT tourist oriented...the 'hidden' 'local' things are what I am really interested in....

By the way, how bad is the Alaska State Bird issue in Anchorage in the summer?

From: John Sehring
Topic: 19187 Message: 19187

Hi All,

Been reading/hearing a lot about better filters for the R-4C receiver.

Question: Do these various mods affect the noise blanker performance?

This can happen due to the effect of bandpass (width, shape, Q) of the narrower filters. Noise pulses get stretched out and the noise blanker can't identify and blank them any more.

This is no reflection on the quality/usefulness of these replacement filters. It's simply a fact of electronic filter life!

I finally obtained and built the N3ZI DDS on Saturday. After configuring the first IF offset correctly, the unit controls the frequency quite nicely. I have it attached to a RCA Y adapter and then connected to the INJ jack of the R4C with the crystal switch set to an unused crystal socket. . I have a significant drop in receiver sensitivity WHICH I assume is due to the low output of the DDS; 250 mV P-P at 200 ohms. Now it's time to figure out how to get the correct output to meet the needs of the R4C. This is a very nice addition to the rig especially when band crystals are $20 per. Doug -N9XTF

John,

If you are referring to the SSB/CW/AM filters then the Noise Blanker will not be affected by adding additional SSB/CW/AM filters. The R4C Noise Blanker resides "before" the SSB/CW/AM filters, not after the SSB/CW/AM filters..

Doug,

You might look at the MAR-6+. Its a nice gain block and works from DC to GHz. I put a sample circuit in the May 2013 Electric Radio (but you won't want the low pass filter). The article is about using the FCC-1/FCC-2 from NorCal to drive a Heathkit DX-60 but should also work for you on the R-4C.

Email me off-list if you need the schematic.

From: VE3AX/7
Topic: 19198 Message: 19198

Evenin' guys:

I just posted a downsized version (1.9 Meg) pic of Ray sitting at the Design Industries desk with his Drake B-line that wowed so many of us back then and ultimately helped bring some of us together here on this group. I know I drooled over that station in the QST ad and when I finally decided to put together a Drake station for good back in the early '90's, it was the memory of this pic that formed the basis of my plan.

Ray sent me an 8 x 10 glossy of the pic used to make that ad about 10 years ago after running into him on 2 meters during some tropo enhancement across the Great Lakes. Of course the talk turned to Drake and his famous ad. This pic arrived totally unexpectedly in the next week's mail.

Ray has given me permission to use it wherever I fell like it so am posting it here. I have a higher quality scan if anyone really needs it. The original scan is a 2.8 Meg PDF file that does a really nice job when printed on a good laserjet with photo paper. The pdf will not load into the Photos album – not sure what the restrictions are – maybe it would go into the FILES section – Garey?

Not sure why, but the bottom of the pic gets cut off in the Yahoo viewer on my little netbook, but am hoping that's an issue with this little beast. The "thumbnail" looks complete.

If anyone has a really god scan of the whole ad, I would love to see that get posted as well. I dumped all my old QST's when I moved out here 7 years ago.

73 and enjoy.

Thanks, Peter.

Anyone recognize the square-framed map on the wall that resembles a Geochron – but isn’t?

I can see why that picture made it into near legendary status. Clean layout, full Drake line-up and a rear-sloping desk to allow for better sight angle.

The +3 I use is essentially a +3B that was rebadged for Lafayette. A rare bird, I've never seen another one. For those that don't know, the "B" is not a circuit revision. It means "all black". IMO it is a much better match for the cosmetics of the TR-7 than the 7077 was. The chrome head and black body of the Super Sidekick would look nice as well. I had one of those many years ago, before the TR-7 came into the house. The SSK is a dynamic mic, so like the Shure 444 it would have a different character than the ceramics. Generally speaking, the reports I got were that the dynamics (Shure 444B and 7077) had a more natural sound that is well suited for casual QSOing, while the ceramic/crystal mics had more "punch" and perhaps better articulation and were more suitable for DX and weak signal work.

You have to keep the gain down if you want to use any amplified mic, since the extra gain isn't needed in the first place. That's why I discourage their use, the exception being the +3. I run mine at about the first dot, with works out to be just a tad above 9 o'clock. That seems to be close in level to my unamplified ceramics. I tend to run between 6 and 9 dB of clipping on the SP-75, anything higher than that becomes objectionable. Since I was using so many different mics I moved the level controls of the SP-75 to the rear panel, using the existing holes to mount new pots with knobs that closely match the 7-Line style. It looks pretty darn good from the rear....

I did have a couple of unsolicited compliments on my audio over the weekend during the DX contest. I was doing S&P, so to have a guy that's running take a pause to compliment my audio seems to mean a little more.

And, here's the Patent for it:

http://www.google.com/patents/US3232038

What's strange is that the map shows the pending patent number, but also a copyright date of 1959. The patent was filed in 1964, then granted in 1966.

This is roughly the time of the first Geochron appearance. BTW, I just acquired a Geochron and mounted it on the shack wall last weekend. It's an amazing device that just can't be duplicated with PC software. I tried with a large Samsung monitor and World Clock software but the Geochron's brilliance is stunning. However, it's definitely an example of "shack excess."

Thanks Peter for scanning and posting the picture. Yep that's one that I remember from the early 70's. What a fabulous looking station, T-4XB, R-4B, CC2 (?) 6 and 2 converters, TC2 2 meter transporter, TC6 6 meter transporter, L-4Basher, W-4 wattmeter, Console (don't recall the model number, C4 maybe), MS-4, and a Shure 444, and the Ham M rotor control.

When I was overseas in the Navy in the early 70's I used to sit on radio watch, read QST, and dream about owning that fabulous station!

I seem to recall a later drake photo of Ray but maybe I'm confused. While I defiantly recognize the horn rimmed glasses picture, I also I seem to recall Ray in another ad, later on, with non-black glasses, and older poofed hair not slicked back. hi hi

That desk is quite amazing. I like the flat writing surface towards the front, and the angled rear portion which angles the radios upward. Is all that equipment actually hooked up? I see a small bundle of cables under MS-4. I would have expected a lot more cabling. Pretty clean set up from a cable point of view.

I don't plan to duplicate that set up but I would like to get the L-4B, especially if I can find one local or within driving distance.

Thanks for the walk down memory lane.

John,

I can't speak with authority with regard to 3rd party filters. But, from what I've read and hear, the noise blanker performance, and alignment of it as well, has the assumption that the basic receiver has been properly aligned. I would assume the same is true for 3rd party filters, but I could be wrong.

Subject: [DrakeRadio] R-4C filter changes

Hi All,

Been reading/hearing a lot about better filters for the R-4C receiver.

Question: Do these various mods affect the noise blanker performance?

This can happen due to the effect of bandpass (width, shape, Q) of the narrower filters. Noise pulses get stretched out and the noise blanker can't identify and blank them any more.

This is no reflection on the quality/usefulness of these replacement filters. It's simply a fact of electronic filter life!

Scott:

Actually came across a 2011 post of you commenting on that ad!

You can see a much more recent pic of Ray here:
http://fdlhams.org/assets/2014-feb_news.pdf

It's almost scary how much he looks like me in that pic. I usually got mistaken for Peter Kormos, a very popular and outspoken MPP for the NDP party in Welland, Ontario, where I worked for 20 years. Google Peter Kormos and look at the pics on the right. A lot depends on whether I'm wearing contacts or glasses. People would come up to me at gas stations in that area and shake my hand! They'd say "Are you Peter? " and of course I couldn't resist saying, "Well, yes I am!" Peter Kormos died suddenly last March – he was 3 months younger than I am!

Couple of corrections – the rx console is the CC-1, not to be confused with the CA-1 which is a stacking cabinet for the 4 line tx/rx. There were two styles of the CC-1, early and late, involving different rear panel plug arrangements.

The 2m rx converter was the SC-2 and the 6 meter was the SC-6. There is a VHF xtal calibrator that went in there too called the SCC-1 and a power supply, the PS-1 (I think that's what it is) to run it all.

As a VHF DX-er since 1970 those Drake transverters were like a dream to me! I was using homebrew 6360 transverters on 2m and 220 Mhz at the time. When I was in Ontario and had the VHF/UHF contest station set up (1998-2007) I would get on with both 6 and 2m transverters barefoot to big, high multi-yagi arrays once in a while and surprise people with the "vintage" station. Here in this deep Rockies valley there's not much point! I have a 3,000 foot rise about 1/4 mile south of me, nearly all of which is in Washington State. Antennas are minimal as well. I still have this dream of moving somewhere, anywhere, with a horizon! Mountaintop homes are rare here, winter access even more rare, and they come with their own set of problems, not the least of which are rattlesnakes (western diamondbacks) and way more black widows than we see down here.

The desk was made by Design Industries, long defunct. I cannot recall what the model is but will work on that. They made the famous Ambassador and President models you see full of Collins gear all the time (logbooks, World's Fair pics). I have an Ambassador (single layer of gear) here that was made for a Drake 4 line – extremely rare! My B-line is in it but it needs some work. The front panel warped when I came west.

I have no idea if the gear is actually hooked up in that pic but I know Ray is in my log on 2 meters way back in the '70's and 30 years later too. Also worked him on HF from the AES Starhip several times over the years.

Fun stuff!

Thanks for your further comments on this, Jim. I might have had the SSK cranked too high when I was using it.

Now I REAALY wish I'd held onto the +3B. It didn't match the coloring of the TS-520, but I agree it'd look beautiful with the TR7.

I think you should give that a try, painting up a few +3A mics. Come up with some story about how these rare collectibles came about.

And if I may offer a suggestion, how about using an EvilBay moniker like, say, "Microphone Mart" where you can flog them for a couple hundred a "pop."

Jus' trying to be helpful.

Brenton Crowhurst, VE6IE

PS actually, I'm not trying to be helpful, and I do not genuinely recommend Jim engage in fraudulent sales practices.
I'm trying to take a humorous swipe at a notorious evil bayer.

Subject: Re: [DrakeRadio] Drake Microphones

The +3 I use is essentially a +3B that was rebadged for Lafayette. A rare bird, I've never seen another one. For those that don't know, the "B" is not a circuit revision. It means "all black". IMO it is a much better match for the cosmetics of the TR-7 than the 7077 was. The chrome head and black body of the Super Sidekick would look nice as well. I had one of those many years ago, before the TR-7 came into the house. The SSK is a dynamic mic, so like the Shure 444 it would have a different character than the ceramics. Generally speaking, the reports I got were that the dynamics (Shure 444B and 7077) had a more natural sound that is well suited for casual QSOing, while the ceramic/crystal mics had more "punch" and perhaps better articulation and were more suitable for DX and weak signal work.

You have to keep the gain down if you want to use any amplified mic, since the extra gain isn't needed in the first place. That's why I discourage their use, the exception being the +3. I run mine at about the first dot, with works out to be just a tad above 9 o'clock. That seems to be close in level to my unamplified ceramics. I tend to run between 6 and 9 dB of clipping on the SP-75, anything higher than that becomes objectionable. Since I was using so many different mics I moved the level controls of the SP-75 to the rear panel, using the existing holes to mount new pots with knobs that closely match the 7-Line style. It looks pretty darn good from the rear....

I did have a couple of unsolicited compliments on my audio over the weekend during the DX contest. I was doing S&P, so to have a guy that's running take a pause to compliment my audio seems to mean a little more.

19213. Plug In Relay for TR-4 Question

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-03-04 21:28:40 UTC
From: <tcantrel@...>
Topic: 19213 Message: 19213

I have a TR-4 that I'm doing some restoration work on and wondered if the Plug-In Relay that Harbach Electronics sells is compatible with the TR-4 wiring and supply voltage ? It's advertised a direct replacement for the TR-4C relay and I realize it takes an adaptor kit to accommodate the relay in a TR-4. Will this work in the TR-4 without a lot of additional modifications or different relay voltage being provided ? Thanks,

Terry, W4WTC

Terry -

I believe the relay that Jeff offers is correct. The relay is a TYCO (P & B) R10-E1-Y4-V2.5k, which is available still from Mouser, Digi-Key, etc. for about the same price. The same relay is used in all the Drake C Series transmitters.
An 'adapter kit' is required, John Kriner (The Man's Amateur Supply) still had those last time I looked. If your original relay is a Varley, you'll need to add a resistor in series with the coil.

The modification kit is a small PC board that mounts over the feedthroughs through the chassis. Not trivial, but easy enough if you follow the directions and keep the wires straight! :-)

Topic: 19217 Message: 19217

Just picked one up on Ebay...supposedly worked 2 years ago, it's been sitting in a closet till I bought it. Seems to be in pretty nice shape, but I can't get it to load up properly on any band, and it only puts out almost 40 watts on 15 meters only...won't load up on any other band. I followed the instructions to a tee, many times. I did set the bias as directed. Im using a dummy load to try it out. One tube was out when I received it, I just plugged it back in, but realize that doesn't mean it's good. They all light up, but that's all I can say. I cleaned all controls and switches with deoxit, and tube sockets. Im trying not to mess with it too much, especially worried about damaging the finals. I'm good with electronics, but have never dug too deep into the Drake units as far as how they're supposed to work (the technical part). Any idea of where to start, what to look for, what to replace? Tube maybe? I don't know where to go
from here. Thanks. John KD2BLY

John,

First, welcome!

Now - don't assume that the finals are good. If you're getting a power peak on 15 only, be sure that it's peaking approximately where it should.

If you have a matching receiver, connect the two together and see if (1) the receiver can receive signals with the TX in control of the frequency and (2) if the TX can output using the RX to control the frequency. The outcome of this will give you a general idea of where the problem may be.

If you have a scope, check for the carrier oscillator signal where it connects to the balanced modulator. You have to key the rig to see this.

The band oscillator should show signals on each band if you attach the probe to the output of the oscillator where it connects to the wafer switch.

Finally, the PTO should show output where it enters the board via the (usually) green and white wire from the PTO.

If the seller was honest and it really was working two years ago, you do not want to start fiddling with the RF trimmers just yet. Check for these signals.

Also, make sure that your XTALS switch is set to NORM.

73 & GL,

Steve Wedge, W1ES/4

OK Guys – you now have no excuse! Your new Drake line will be “wife-approved” and will look right at home in your living room!!!! Imagine! You in your grey suit, pipe hanging from your lips, and your darling wife in a DRESS, sipping her post-dinner coffee and watching you work DX!

All you need is the Design Industries desk; a Diplomat like Ray’s at only $139, or the upscale Ambassador, and you can start your next DXCC right from the living room! A dream come true!

OK – that was 1965 – good luck with that nowadays! Unless you’re a bachelor. I am not.

I have posted 2 ads and W2NSD’s review of the Diplomat in my pics files. They are taken from a web post of 73 Magazine, dated Oct 1965. Hopefully you can read them. Note the radios on the desk in Wayne’s review! He knew what he was doing.

Not the best resolution but it should do for now. A bigger monitor will help. Once I find my full colour Design Industries catalogue I’ll re-scan and post others.

Have fun!

I've had a little fun lately with my TR7 on 160 mtr. AM. A fellow in Oklahoma runs a converted broadcast transmitter and a Collins receiver with an outboard synchronous detector. Claims it makes the TR7 with its SSB full carrier sound tolerable. Give it a try. The gang on Top Band will always welcome newcomers. I tune a qtr. wave wire that I launched up into the pines with a slingshot. That and a good counterpoise and you are in business. Actually that's a noisy receive antenna, but it will get you started.

I dunno Peter. Putting that desk in the living may more likely be "divorce approved" rather than "wife approved" hi hi That desk is very nice looking though! When the time comes to have the shack on the main floor I'll have my brother-in-law make me one. I have my own radio room in the basement, and the rule is that nothing crosses the line at the door to be stored in the finished basement.

From: Jim Shorney
Topic: 19215 Message: 19227

Heh... We'll blame the email program.

The TR-7 has been modified to use the 6 KHz filter on AM for transmit. I actually had this idea some years ago, but Jeff Covelli WA8SAJ beat me to the punch in implementation and published this article:

http://www.wb4hfn.com/DRAKE/DrakeArticles/TR7_AM_Mod/TR7_AM-P1.htm

That's the basic mod. It can, of course, be adapted to use whichever filter slot your AM filter is in. I adapted it to switch the wide filter in automatically on AM transmit via a small SMT relay hot-glued "dead bug" style to the bottom of the parent board instead of using the "Store" switch as Jeff did. I also improved the mod in that Jeff did not include a method to properly center the TX signal in the filter passband. Probably a trivial omission, but it bugged me. :) It was simpler than it sounds, just about everything needed to accomplish it was already there. IIRC I posted a note to Drakelist after I did it. I don't think anyone noticed....

The op at W1AW/7 was Paul KW7Y, and he was operating remotely from California. His signal was strong and clear on both 15 today and 10 last Friday, and the audio was quite good. It was a bit on the surreal side hearing W1AW/7 with a British accent coming from my speaker so clearly.

I got an idea why his signal was so good when I looked at this:

http://myplace.frontier.com/~paulbaldock/camano/

I spotted three pieces that I also own in his commercial boatanchor pic. No Drakes, sadly.

19228. Trade 28.5 for 28.0 Crystal

Yahoo group: DrakeRadio (2014-01 — 2014-05)
Date: 2014-03-05 04:42:00 UTC
From: <rochep@...>
Topic: 19228 Message: 19228

My new Drake R4A came with a 39.6 MHz crystal (for 28.5-29 MHz), but I do not operate phone. Anyone have a 39.1 MHz crystal (for 28.0-28.5 MHz) to trade? (Maybe you are phone op and have no interest in CW.)

Email Paul at k3stx@arrl.net

19229. Re: [DrakeRadio] Ray Grenier's K9KHW AES & Drake QST ad

Scott:

I get a kick out of that “wife-approved” slogan they used in their ads. I have to wonder how many guys actually got their wives to agree to putting their “shack” in the living room. One of the CCA guys has a lovely looking house with a gorgeous shack in HIS living room, but there appears to be no wife involved. My wife’s a ham (VE7DR/VE3EMS – my original call) of 23 years now (married 38 yrs) but there is still no way there’s a radio going in the living room unless it can play CD’s. I did manage a restored Radiola 18 that resides in the hall between the living and dining rooms, but that was a gift to my elderly parents some 10 years ago that has come back to us.

I managed to find the original AES ad in a 73 Mag from November 1970 on the net and it is now included in my Photos section. Hopefully I haven’t violated any copyright laws.

My shack is in a separate building 75’ from the house. The service bench is in the basement though. Both are finished. Storage areas for radio parts/gear is a constant state of “negotiation” and upheaval however! I know well what you mean about crossing that line!

Now this bit of advice is off topic but will throw it in here seeing as we’re talking about shacks – do NOT use fiberglas insulation if you’re trying to keep radio audio from the rest of the house. Use mineral wool fibre , also known as stonewool. It is fireproof, rodent proof, mildew resistant, and has absolutely astounding sound deadening qualities. I use it every where I can and would never use fiberglas insulation again for an interior wall or ceiling. How do I know? I work for one of the companies that make stonewool , and before I did, I wasted my money on fiberglas for interior insulation. Never again! Both my shack and my service area are lined with the stuff in the walls and ceilings.

Subject: Re: [DrakeRadio] Ray Grenier's K9KHW AES & Drake QST ad

I dunno Peter. Putting that desk in the living may more likely be "divorce approved" rather than "wife approved" hi hi That desk is very nice looking though! When the time comes to have the shack on the main floor I'll have my brother-in-law make me one. I have my own radio room in the basement, and the rule is that nothing crosses the line at the door to be stored in the finished basement.

There's an amusing thought.

I actually know a guy who does repaints on pro-audio mics. He used to work in our Electro-Voice service area. I was thinking of having him do a black RE-20 for me, but then I stumbled into some RE-320 parts and built my own. He has one of my orignal gray +3s that he re-painted in a sort of hammertone gray for me. I need to get that from him and re-assemble it. I'd like to have him re-do my "Lafayette Range Boost" +3B, but I would need a good way to reproduce the markings for the level control.

I have also done the am mod as described in the Jeff Covelli article:

http://www.wb4hfn.com/DRAKE/DrakeArticles/TR7_AM_Mod/TR7_AM-P1.htm

and did as Jim said about centering the passband:

https://www.mail-archive.com/drakelist@.../msg09892.html

Also used a small signal relay to switch in the
wide band mod instead of using the store button.
Pin 11/36 on the 2nd if/audio board provides 10v
on AM transmit and was enough to operate the relay.

Now AM is perfect DSB with carrier and I have also received good audio reports.

From: Garey Barrell
Topic: 19232 Message: 19233

Paul -

Yes, all V and R measurements are to chassis. Be sure and follow control setting specifications. Also note that they
are made with a VTVM. It DOES make a difference on quite a few measurements.

The typical DMM uses far less current for resistance measurements, and polarity varies from model to model. So if a
reading is 'off', first reverse the meter leads. If still off, LOOK at the circuit and see if there are parallel paths.
Finally, if the measurement includes the power supply bus, all bets are off! Finally +, when circuit changes were made,
the V and R tables weren't always changed as well. Some are easy to spot, e.g., the Cathode pin that is connected
directly to ground, but shows 250 ohms on the table! There 'usta' be a resistor there. Personally, I don't use the
resistance tables at all.

Also, voltage measurements were made with a VTVM. The only hang-up is Grids of oscillators. Here the loading of the
DMM _lead_ will kill many oscillators, upsetting the bias and therefore the expected voltage. This is obviated by the
1M resistor at the tip of VTVM DC probes. If you don't have a VTVM, you can stick a 1M (or so!) resistor on the tip of
the DMM probe and consider the error introduced.

Biggest DMM-caused problem ... Measuring resistances and voltages to two decimal places and fretting over the 2%
variation from the table! Plus or minus 10-15% is just fine for most all.

In a word, yes. BUT, bear in mind that your readings with a DMM may be somewhat different due to differing excitation voltages used with DMM's vs the old Simpson 260 meters that were likely used to create the charts.

Topic: 19235 Message: 19235

I'm getting an old friend back into shape. My TR4CW was shelved for several years due to "no audio". Many thanks to Garey for steering me to the Bogen T-175 audio output transformer. It's working great on the green tap. For access to the transformer mounts I removed the PTO, and while it was out I gave it a full PM. Now silky smooth. Receive is fine. Only issue is excessive drive on transmit. I just can't throttle this thing down in CW mode by using the transmitter gain control. Plate circuit loads properly and produces rated output at proper plate current, just can't QRO. CW is clean, low SWR (no apparent parasitic issue in the PA). The Xmit gain pot is good. PA bias adjusted to .1A. No attempt was made at alignment. NOTE: I noticed this problem prior to audio transformer/PTO work, so I did not just introduce this issue. Seems to have crept in during dormancy. Any thoughts gang? Thanks. N5LAZ

19236. RE: Resistance measurements

From: <w5rkl@...>
Topic: 19232 Message: 19236

Not always. It depends on the circuit. You should use the schematic along with the resistance chart when measuring resistance.

You should also learn how to measure voltage drops across a component such as a resistor and then use that voltage drop to determine a voltage at a junction of 2 resistors. It's very easy to do. Here's a simple example with 3 resistors in series connected across a 12VDC source, power supply or battery.

The 3 resistors are 1K, 2K, and 3K. The source voltage is 12VDC. While you can do the simple measurement using the DVM/DMM or VTVM, and connect the meter to measure the voltage drop, if you use Ohms Law you will learn more.

First, calculate the total resistance which, in this circuit, is 6000 ohms (1000 + 2000 + 3000 = 6000).
Next you calculate the total current flowing in the circuit which is .002 amps

12 / 6000 = .002 amps

Next, you calculate the voltage drop across the 1K resistor and that would be "2 VDC"

.002 x 1000 = 2VDC

Next you calculate the voltage at the junction of the 1K and 2K resistors which is 10 VDC

12 - 2 = 10

If you connect your DVM/DMM or VTVM RED lead to the 12VDC positive terminal and the DVM/DMM or VTVM BLACK lead to the junction of the 1K and 2K resistors you will see "2VDC".

Next, what is the voltage drop across the 2K resistor and what's the voltage at the junction of the 2K and 3K resistors?

That's easy, it's 4VDC.

.002 x 2000 = 4VDC

The voltage at the junction of the 2K and 3K resistor will be 6VDC.

10 - 4 = 6VDC

Connect y9our DVM/DMM or VTVM across the 2K resistor and you will see "4VDC".

Sorry for being long, just thought this might be of interest to those who are learning the basics.

Leon -

Assuming the output you are seeing is on frequency, (where it's supposed to be,) possibly a bad ground on the XMTR GAIN
control. Or an open circuit inside the XMTR GAIN control. This is a two section control, one section adjusts the SSB
mic gain, the other section adjusts the unbalance of the Balanced Modulator for CW.

Does the SSB part work ok? Idle current, increasing with modulation?

Date: 2014-03-05 17:11:36 UTC
From: Barry
Topic: 19232 Message: 19238

Ratios work just as easily. 1K is 1/6 of the total resistance so it will have 1/6 of the total voltage dropped across it (1/6 X 12V = 2V). 2K is 2/6 (1/3) of the total resistance so it will have 1/3 of the total voltage dropped across it (1/3 X 12V = 4V) and so on.

Of course, the Ohm's Law methods need to be understood but sometimes it's easy to take some shortcuts.

Preachin' to the choir...

Thanks,
Barry - N4BUQ

SSB works fine. Proper idle current. Carrier suppression good. Output fine with proper IP deflection, ALC action, and watts out. Sounds good on monitor receiver. It seems the only issue with this radio is that it will not QRP in Tune or CW (with key closed). If I detune the preselector I can QRP enough to see effect from the Xmit gain pot, and it seems to work across its range. But with preselector peaked, Xmit gain pot cannot bring power down. Breaking out the schematic I see a regulated +150 volts feeding the pot. Will check that and wiring.

Assuming the output you are seeing is on frequency, (where it's supposed to be,) possibly a bad ground on the XMTR GAIN
control. Or an open circuit inside the XMTR GAIN control. This is a two section control, one section adjusts the SSB
mic gain, the other section adjusts the unbalance of the Balanced Modulator for CW.

Does the SSB part work ok? Idle current, increasing with modulation?

Leon -

Still say bad ground on the CW portion (R74), or element open at full CCW. Along with R75 forms a current source
applied to the BAL MOD. This current through the diodes unbalances the BAL MOD, allowing the CO to go through.
Intended operation applies voltage through R75 to the wiper of R74. Current is increased as the pot is rotated up
(CW). If the ground, (or element is open at the grounded end,) the 500k of the pot is just in series with R75, limiting
the current 'somewhat'.....

Let us know!

With wafer sw. set to cal position, gain pot fully ccw, resistance readings to ground are: 496k on far non-grounded end. 12.8 ohms on center terminal and 0.1 ohm on grounded terminal. Center terminal goes to 210k at full CW. Wafer contacts show 0.8 ohm between top of R74 and constant contact terminal when in X-CW position. 150v Reg. is good.
